Therefore, the first step towards the enhancement of ICT adoption in the construction context includes generating the necessary motivation amongst practitioners and policy makers through disseminating the knowledge about currently-available methods and highlighting the potential benefits (Sarshar & Isikdag, 2004; Williams, 2007). To address such need, this chapter aims at introducing available cutting edge methodologies applicable to construction activities. The useful feature of this chapter is that it brings information about different cutting-edge methodologies under one cover. The content of the chapter is designed for readers who might not be specialists in ICT-oriented techniques while working within any domain of the construction industry. In the classroom, this chapter could be a supplementary source for courses on information systems in construction or lean project delivery.

The chapter starts with a brief discussion on the driving forces and root causes of rapid advances in the tools and technologies utilized in the con-

struction context. This is followed by describing the concepts of virtual design and construction (VDC). Afterwards, different aspects of building information modelling are discussed. The rest of the chapter is concerned with introducing various innovative AIM that are emerging within the construction industry.

BACKGROUND

The driving forces pushing the construction industry towards adopting AIM for the most part have roots in two main categories of drivers. These include the efficiency needed to proactively addressing internal process problems facing the industry alongside pressures from the external environment (Cao et al., 2014). In essence, the main reasons behind the interest of construction practitioners to adopt advanced ICT methods come from three main grounds under two categories:

1. External pressure
 - a. Fierce competition of globalisation (external pressure)
 - b. New requirements of projects (external pressure)
2. Internal problems
 - a. Advantages of advanced ICT methodologies (efficiency needed to address internal problems)

As illustrated in Figure 1, the capabilities of AIM in terms of facilitating achieving efficacy in delivering projects by integration of design and construction phases as a main reason for construction companies (Aouad, Lee, & Wu, 2007). In this regard, enhancing collaboration level, facilitating accessibility and exchange of information and enhancing the effectiveness of communications has been acknowledged (Nitithamyong & Skibniewski, 2004). Besides, many studies have attested to the positive impacts of utilising ICT in the construction industry on grounds of improving cost-effectiveness, scheduling and quality of products (Williams, 2007). In the same vein, ICT

implementation has far-reaching positive impacts on all major aspects of AEC projects including time, cost, competitiveness enhancement and information exchange (Hosseini, Chileshe, Zuo, & Baroudi, 2012). AIM are deemed the most promising tool for organisations in today's market. That is, they are regarded as a catalyst for process improvement through providing the ability for construction companies to share multi-disciplinary interests, goals, perspectives, and constraints in an accurate, timely and economical way (Aouad et al., 2007). As such, there is consensus regarding the positive effects of utilising AIM in construction organisations and on projects (Adriaanse, Voordijk, & Dewulf, 2010). Moreover, the cost of adoption AIM on construction projects is continuously declining (Sardroud, 2015). On top of that, technologies that support AIM are progressively advancing in other fields. These result in AIM redefining the methods and procedures in the construction context, thus bringing a paradigm shift into the practices of the construction context (Hardin & McCool, 2015).

In this context, a wide range of AIM have emerged under the framework of VDC (Khanzode, Fischer, Reed, & Ballard, 2006) as will be described next.

Virtual Design and Construction

The VDC concept emerged out of the attempts to apply lean production principles to the practices of the construction industry in delivering projects. The birthplace for VDC was the Centre for Integrated Facility Engineering (CIFE) at Stanford University where VDC was officially introduced in 2001. CIFE has remained a magnet for research and teaching on VDC since then (Kunz & Fischer, 2012). As defined by CIFE, VDC is the application of multi-disciplinary performance models of design/construction, which include the *Product* (i.e., facilities), *Organization* of the design, and *Processes* referred to as POP in order to support business interests. In essence, VDC tools enable construction practitioners of simulating construc-

Figure 1. The major driving forces behind the emergence of AIM within the construction industry
 Source: adapted from Hosseini & Chileshe, 2015

tion project models as the composition of related models of Product, Organization and Process or POP as asserted by Garcia, Kunz, Ekstrom, and Kiviniemi (2004). This benefits construction practitioners by, automation, integration, and visualization of construction activities in particular to predict project outcomes and manage the project towards the desired performance (Yee, Fischer, & Kam, 2013).

Adopting VDC could be advantageous in every stage of a project even during the bidding and preparing the tender documents by increasing the accuracy and efficacy available information and data. Rich visualised representation of data could be used to effectively communicate complex technical information and illustrate predictable circumstances that are likely to occur in the real projects through a virtual environment. This will

enhance effective communication of concepts and designs for all the stakeholders. Based on the concept of POP as discussed above, Khanzode et al. (2006) introduced the most well-known available AIM under VDC as illustrated below.

- Product visualization tools or 3D object modelling, which can create a common understanding among various discipline on how the completed product of the project (e.g. a building) will look like. 3D models will facilitate coordination of design among different disciplines as well.
- Product+ Processes visualisation tools, which present a visualisation of the processes for completion of the product based on 3D models. These tools will add a di-

mension of time to 3D models and are usually referred to as 4D (3D+ Time = 4D).

- *Organization+ Processes* tools that simulate the effort needed for completion of the projects and assist stakeholders in identifying organizational risks. Online collaboration tools fall within this category.

Apart from this, the concept of *nD* model is used in the literature for referring to visualization models in which information required for various stages of a project are embedded (Aouad et al., 2007). Such models could contain information regarding material resources integrated with the scheduling and cost data, termed as 5D (Lu, Won, & Cheng, 2015). All such visualisation models are in fact created through Building Information Modelling (BIM) as described below.

Building Information Modelling (BIM)

Building Information Modelling (BIM) has been evolving since 2003 with no clear starting point found for the commercial introduction of BIM (Holzer, 2015). In today's business environment BIM could be regarded as the most promising ICT-oriented development in the construction industry (Eastman, Teicholz, & Sacks, 2011). BIM involves collating, applying and maintaining an integral digital representation of all building information for different phases of the project life cycle in the form of a data repository (Gu & London, 2010). It provides a comprehensive concept as an umbrella for the processes and tools, which integrate all projects required data through containing information needed in particular phases of a building's life-cycle (scheduling, analysis, cost evaluation, etc.). Yet, BIM is much more than a data container for the building model; it is an object oriented building design and construction-specific model to assist the progress of the exchange and interoperability of data in the digital format (Babič, Podbreznik, & Rebolj, 2010). A major benefit of utilising BIM in the design and construction phase of a project is obviously coming through its ability to 'model' and test the constructability of

the design within the model prior to setting foot on the project site. As a management paradigm, BIM can be implemented through chains of ICT technologies including BIM authoring tools such as Revit, ArchiCad, Microstation and Navisworks.

Implementing BIM helps to avoid errors alongside improving the productivity, scheduling, safety, cost and quality of construction projects (Zuppa, Issa, & Suermann, 2009). BIM is a fast and effective process by which information pertaining to one project can be updated at any stage of project from any department or unit (e.g. engineering department). Accordingly, because of its efficiency in adopting and propagating changes in the model, editing objects and reloading updated links, the entire project model will be updated based on the changes on one aspect of the project. It is asserted that BIM is capable of enhancing the performance within the industry along with overcoming the problems stemmed from the fragmented structure dominating the industry (Succar, 2009). As an emerging method within the construction context, BIM entails managing data flows in different natures between different parties (Succar, 2009) by manifesting a virtual working environment (Fox & Hietanen, 2007; Howard & Björk, 2008). Serving a catalyst of change for the construction industry, BIM encompasses a radical reorientation of 2D to 3D modelling and a recent shift to 4D (project scheduling integrated), 5D (project cost integrated) and 6D (facility management integrated), exploiting more intelligent data analysis techniques in order to achieve a superior performance in delivering an As-Built BIM. In this context, ICT should supply the platform for BIM to pursue its trend becoming a mainstay of research and development in the construction industry (Singh, 2014).

ICT and Sustainable Built Environment

The construction industry is progressively discovering how ICT tools can help the construction industry to attain more sustainable outcomes. ICT is capable of providing a unified approach in

storing, transmitting, sharing and distributing data among the parties involved in the built environment context. The advantages of incorporating ICT in fostering a sustainable built environment include:

- Facilitate the rule-based checking of sustainability guidelines,
- Find and retrieve environmental solutions,
- Increase the speed and efficiency of sharing green principles, and
- Decrease the environmental impact by underrating the paperwork and waste generation.

One example for integration of ICT into sustainable construction could be the powerful visualization engine of BIM, which envisages any technically possible way of creating or testing “what if” scenarios during the sustainable building procedure (Banihashemi Namini, Ding, Wang, & Jack, 2015). Beyond graphically depicting the design, much of the data needed for supporting sustainable building is captured naturally as design of the project proceeds. It paves the way of superimposing multidisciplinary information in an integrated model creating an opportunity for measuring the sustainability state of the project throughout its lifecycle (Azhar, Carlton, Olsen, & Ahmad, 2011). According to Krygiel and Nies (2008), BIM has the potential to aid sustainable design through:

- Selecting a suitable building orientation,
- Evaluating building envelop,
- Day-lighting analysis,
- Water needs reduction in a building,
- Integration with energy analysis software to reduce energy consumption,
- Featuring renewable energy possibilities,
- Material needs reduction,
- Decreasing waste and carbon emission by logistic site management.

Architects can import data into BIM model to locate the project geographically and present the

conditions of climate, location and surrounding area. Then, the model can be reoriented and edited on site based on the real coordination for reducing required resources and exposing efficiently to solar radiation (Eastman, Teicholz, & Sacks, 2011). Engineers utilize BIM to decrease the energy consumption by exporting the 3D model to particular energy analysis software and calculating light reflectance and transmittance (Underwood, Isikdag, & Global, 2010). Effectively coordinating logistics through site analysis and modelling including wetlands and protected habitats can help contractors to eliminate the possible issues and even easily quantify the amount of materials extraction of buildings to simplify reusing or recycling measures. Finally, the BIM file arranges an array of required resources to advise the project team regarding sustainability issues from the incipient stages of a project (Hardin, 2011).

Smart mechanisms such as smart metering and sensor network-based sub-utility measurements are among the emerging ICT technologies that will be rapidly developing in the upcoming years. These devices are capable of measuring energy usage more precise than the current instruments and also transmitting the detected information via networks. This system will allow for better energy consumption records in both temporal and demand profiles as well as supplying the novel digital platforms for different stakeholders including energy performance benchmarking, load forecasting and consumption monitoring for residential buildings (Ahola, Ahlqvist, Ermes, Myllyoja, & Savola, 2010). Provision of these services enables all parties involved to apply environmentally sound principles in energy usage reduction, enhance energy efficiency measures and in the long run, integrate with other ICT tools like smart appliances and building automation systems.

Virtual Reality

The term ‘virtual reality’ (VR) has been used in the literature for more fifteen years. The expression VR was introduced for the first time in the

US in the 80s by Jaron Lanier and became a common name. VR is simply defined as providing a cognitive activity in an artificial digitally-created world. Such a world is symbolic, imaginary and is literally a simulation of certain aspects of the real world with attributes copied from the real world (Fuchs, Guitton, & Moreau, 2011). For the construction context, VR presents a natural medium for a building design and provides 3D visualization, which can be manipulated in real-time and deployed in a collaborative manner in order to explore all stages of the lifecycle of construction projects. The applications of VR for the construction industry are diverse and target a wide range of audience. That is, VR greatly benefits the construction industry through providing (Dawood, 2009; Nikolic, Jaruhar, & Messner, 2011):

- Greater level of safety on construction sites,
- Enabling construction practitioners to test alternative construction techniques and methods by simulation and visualisations of all alternatives,
- Evaluation and assessment of available information in a virtual environment
- Allowing an accurate sequencing of operations,
- Presenting novel approaches for collaboration and communication between parties involved on projects and
- Education and training of students

Augmented Reality

Augmented Reality (AR) is a powerful user interface paradigm that enhances a user's perception by inserting computer-generated information into a user's real world experience. Construction practitioners need to make decisions frequently on onsite work environment. This necessitates access to mobile visualization technology as well as being grounded and aware of the real construction site context. This has become the primary driving force behind increasing adoption and

promise of AR compared to VR. That is, AR is a tool capable of supplementing reality instead of replacing it. AR is the *middle ground* between a purely virtual environment and a completely real world (Lin, Liu, Tsai, & Kang, 2014). AR has been employed for a wide range of applications in the construction industry. These include maintenance, manufacturing, training, 3D video conferencing, computer assisted training and instruction, entertainment and construction design. Using AR, a construction practitioner will be able to combine the 3D object into the normal viewing perspective without losing any of the advantages of object movement and individual movement in a real-world environment. When it comes to BIM, AR is envisaged to become the tool to convey BIM in an effective manner on construction sites described as extended hand for BIM (Wang, Truijens, Hou, Wang, & Zhou, 2014).

Drones

A drone is an aerial vehicle without on board pilot officially termed as Unmanned Aerial Vehicles (UAVs). Drones came into public attention due to their recent applications in military operations and their civil applications predominantly in the agriculture industry (Nonami, Kendoul, Suzuki, Wang, & Nakazawa, 2010). Drones offer major benefits when used for aerial surveillance and inspection in complex environments such as construction sites. Application of drones on construction sites is very recent and limited to below activities.

- Assisting safety management for which drone acts as a safety officer and controls and monitors a number of workers. It assists safety managers to spot safety issues on the site quickly (Irizarry, Gheisari, & Walker, 2012).
- Drones assist site managers by picking up the signals emitted by Radio Frequency Identification Technology (RFID) tags and provide information on the location and

movement of tags. The data could be collected to be used in BIM models (Hubbard et al., 2015).

- Drones can be flown to certain altitudes and locations for capturing images. The images can be used to develop 3D illustration by the use of AR technology.
- Surveying for which drones can be used in surveying activities with difficult access to objects such as landfill, pits, stockpile, quarries, surface mining areas and slopes. Drones are efficient and can complete surveying activities in shorter times, at lower costs, with fewer number of personnel and in higher levels of accuracy.

Geospatial Information System (GIS)

The concept of GIS emerged in the 60s in Canada. GIS is defined as a tool that is utilised to assist people in acquiring spatial information and learn about geography. That is, storing spatial data in digital formats provides rapid access for a wide range of purposes (Fazal, 2008). When the performing area of construction site is vast, a single BIM model may not be a good fit to handle all the existing objects and facilities. Considering a large-sized construction zone with a lot of buildings and recreational facilities with myriad trees and green spaces would make it hard to think about implementing all the substances on a single model. Working with such a model would be hard, time consuming and vulnerable to flaws. Thus, the BIM approach needs to use a reliable and comprehensive context in order to link different BIM models and their information and provide an integrated and powerful decision support system for both project managers and stakeholders to handle the whole area of the project at hand. GIS provides a reliable tool based on its precise coordination system and geospatial integrity for as many different BIM models as possible (Mignard & Nicolle, 2014). With GIS, the entire most recent detailed data about every single project becomes readily available. Moreover, GIS would let the owners

to have cumulative information about the whole project data including elapsed and remaining costs, time and required materials. This would help them have remarkable ability toward decision making and expenditure control. Therefore, bundling GIS with BIM would bring remarkable potentials for managers in large-sized construction projects.

3D Terrestrial Laser Scanning (TLS)

There is a great need within the construction industry for automating the inspection of projects. Among all available methods, 3D Terrestrial Laser Scanning (TLS) has found to be the best available method to capture 3D information on a construction project with high levels of accuracy in high speed. TLS is defined as a modern measurement technology that is revolutionizing dimensional surveying in the construction industry particularly in the facilities management field (Bosché & Biotteau, 2015). TLS has been a promising technique in the construction industry, which enables construction practitioners of tracking their progress, controlling quality, monitoring health and creating 3D as-built models for managing facilities (Bosché, Ahmed, Turkan, Haas, & Haas, 2015). One of the recent advancements has been the emergence of interfaces between BIM models and models created by TLS.

3D Printing

According to Cano (2015, p. 3) “3D printing is basically a type of additive technology manufacturing, which means that instead of starting with a solid block of material and cutting it down to a shape, an object is built by adding one layer of material at a time.”. 3D printing falls within the category of rapid manufacturing methods, which have permeated the construction industry. 3D printing based on inkjet technology is a common method in which the inkjet selectively deposits a binder in form of liquid onto a bed of powder. The role of the binder is to glue the powder together (Buswell, Soar, Gibb, & Thorpe, 2007). The

construction industry is moving toward using utilization of manufacturing methods for which construction components could be printed on site followed by assembly. Printing components such as concrete parts have become common and experienced in detail, yet printing large construction components or full-scale units are in their infancy stages (Lim et al., 2012).

FUTURE RESEARCH DIRECTIONS

Future researchers would contribute to the construction industry body of the knowledge through attempting to integrate the different AIM within the lifecycle of construction projects. That is, at the moment applications of AIM on projects are piecemeal and disjointed, thus a major part of the potentials is lost. Integration of AIM within each other under the umbrella of VDC can assist construction practitioners in gaining the full potentials envisaged for using AIM. A rudimentary effort has been presented here in Figure 2 to show

a sample of delivering a construction projects in 3 main phases utilising an integrated AIM.

Therefore, further research studies should concentrate on ascertaining the most effective policies to lead construction practitioners towards harnessing the benefits of adopting integrated AIM in different stages of construction projects. To this end, future inquiries should present frameworks for facilitating managing change in construction organisations. A deep appreciation of the dynamics of change at the people/technology interaction is a prerequisite for the successful implementation of integrated AIM on construction projects. This could be a fertile ground for future investigations. Additionally, mapping the status of universities and the levels of skills and knowledge of graduates in regards to using each of AIM elements particularly BIM should be considered as a subject for future inquiries. Such explorations should compare the pertinent requirements in the industry against the abilities of graduates and the content of university programs and accordingly spot the gaps and shortcomings in this area.

Figure 2. Delivering a construction projects through an integrated AIM

CONCLUSION

The construction context has yet to harness the benefits of AIM effectively, due to many barriers hampering the shift from traditional methods to AIM. The major barriers include cultural and organisational resistance coupled with the lack of knowledge in the industry. Hence, it becomes incumbent to practitioners and researchers to foster the culture of adopting AIM and promote delivering projects through integration of AIM as described in previous sections. One remedial solution for this might be conducting research studies to spot the true impediments towards uptake of AIM in construction organizations and projects. In the same vein, procedures of merging AIM into construction activities and processes would be facilitated by incorporating the principles of established theories associated with innovation adoption. To this end, inquiries should consider building upon robust theoretical foundations such as principles of Innovation Diffusion Models (IDMs).

KEY TERMS AND DEFINITIONS

Construction Industry: The term represents architecture, engineering, and construction i.e. all sectors that provide architectural design, engineering design and construction services.

ICT: Stands for information communication technology and concerns any technology or product associated with storing, retrieving, manipulating, transmitting, or receiving information electronically in a digital nature.

ICT in the Construction Context: This covers goods (such as office software suite and communication equipment), services and management (such as telecommunication including transmission and display) adopted to generate growth and improve productivity in the construction context.

Innovation: Innovations for the construction context represent the profitable developments and implementation of novel ideas, procedures, products, and practices geared towards enhancing organisational performance.

Amplifying the Significance of Systems Thinking in Organization

B**Mambo Governor Mupepi***Grand Valley State University, USA***Sylvia C. Mupepi***Grand Valley State University, USA***Jaideep Motwani***Grand Valley State University, USA*

INTRODUCTION

The reality in organization is that learning never stops. People in the organization can be taught to think alike about the job at hand. Systems thinking is pervasive in highly productive organizations. Effective teams can be well-coordinated in their specific roles in the value creation system. Job specifications and descriptions are akin to tele-prompters in aiding individuals to do the right thing first time and always. They are part of the documentation necessary in successful organizations. Individuals groups and teams must learn their roles and understand what gives life to the organization. The sociotechnical conceptual model provides a description of perceived reality. It gives a systemic content of inquiry and views the organization as an open system model, a purposeful conceptual part or whole organism. Koestler (1967) coined the term *holon* to imply something that could be described simultaneously as a whole or part. Divisions or units in organization can be viewed as *holon* because they can be corporations in their own right and at the same time they can be *owned* by another corporation.

An Interdisciplinary Origin

A system is viewed as a whole whose elements hang together because they continuously affect each other over time and operate toward a

common purpose. In Stichweh (2010), systems theory is defined as an interdisciplinary study of systems in general, with the goal of discovering patterns and algorithms necessary in maintaining the value creation system to produce the goods and services demanded by the customers. Stichweh elucidates the definition of systems theory as an understanding related to the General System Theory of biologist Ludwig von Bertalanffy (Bertalanffy, 1934), physiologists Walter B. Cannon, Walter Pitts, Warren McCulloch and cybernetics technologists Claude Shannon, Norbert Wiener, and William Ross Ashby. In Daft (2013) a group of technocrats from the same organization referred to as skunkworks meet regularly in defined physical places and in cyberspace to progress organizational goals. Daft argued that the skunkworks were a people who shared the same vision about their organization. They deliberated in designing new products and appropriate technology to make those new products a reality. In Gharajedaghi (2010) systems thinking is deployed in the search for solutions to the problems the organization faces such as competition. How to effectively compete can be framed by co-constructing a shared vision of the future. Systems thinking can be applied to design and implement the competitive advantage.

 Source: Mupepi, 2017

BACKGROUND

Action Research: A Lewinian Approach

The sociotechnical systems is founded on action research (Lewin 1946) as its basic process of inquiry or purposeful human activity *holon* (Eijnatten, 1993). The Adam Smith Pin Factory is revisited to illustrate how the novice can increase their skillfulness and explicit knowledge to become specialists. The conceptual framework provides an opportunity to envision the techniques and tools essential in developing the explicit practices required in effective organization. Following the work of Adam Smith in Mupepi (2014), structures are viewed as open systems molded and determined by values and norms. They also contain job descriptions job specifications and techniques needed for the structure to make meaning contribution in the value creation process. The pin-production open system provides an opportunity to understand the explicit knowledge needed to increase output (see Figure 1). In Systems thinking the organizational structure is viewed as the pattern of interrelationships among key actors. It includes the value

creation process and hierarchical chart, attitudes and perceptions, quality of products, ways in which decisions are made and how things are done. Systems dynamics demonstrate the interdependence of each position and task, and how they are all related to whole production department or *holon*. The art of sociotechnical systems thinking includes learning to recognize the ramifications and trade-offs of the actions members choose to follow (see Figure 1).

The historical development of sociotechnical systems design (STSD), can be argued to have roots in London's Tavistock Human Relations Institute before WW2. Trist & Bamforth (1951) attribute the first studies conducted by Fred Emery in the British coal fields in Yorkshire and Norwegian industries (Emery & Trist, 1981). These studies resulted in the development of effective STSD approach as a collaboration effort of many scholars including Lewin, Lippitt & White (1939), Bion (1949), Cummings (1978), and Eijnatten & Hoevenaars (1989), among many others. Sociotechnical systems thinking is espoused from STSD and the systems theory developed by von Bertalanffy (1969) and Lewin (1946) respectively (Eijnatten 1993).

Group Dynamics

Kurt Lewin (1943) is commonly identified as the founder of the movement to study groups scientifically. He coined the term *group dynamics* to describe the way groups and individuals act and react to changing circumstances. In Backstrom, Huttenlocher, Kleinberg & Lan (2006), group dynamics is a system of behaviors and psychological processes occurring within a social group (intragroup dynamics), or between social groups (intergroup dynamics). The study of group dynamics can be useful in understanding decision-making behavior, how the job is thought out and implemented and tracking the value chain to appreciate bottlenecks in efforts to increase productivity. In Bion (1949), alludes to idea that the software of a group's mind can be seen in thinking alike or systems thinking. Wilfred Bion's observations about the role of group processes in group dynamics are set out in a book entitled: *Experiences in Groups* first published in 1962. In this book Bion refers to recurrent emotional states of groups as basic assumptions. Bion suggested that the work group was interested in the aspect of group functioning which had to do with the primary task of the group—what the group has formed to accomplish. The primary group kept the organization anchored to a sophisticated and rational level of behavior. The secondary group was concerned with sustenance by the leader. The group was dependent on its leader for material and spiritual resources. In later research Salas & Diazgranados et al (2008), posit that groups could focus on aligning around goals, building effective working relationships, reducing team members' role ambiguity and finding solutions to team problems. Salas & Diazgranados add to the group dynamics discourse by adding performance factors: setting goals, role clarification, problem solving, and interpersonal relations to increase organizational effectiveness.

Transformative Small Groups

Many on-job training techniques have been adapted from the research conducted in many places including Tavistock Institute and T-Groups at National Training Laboratories at Bethel, Maine (Gallant & Rios, 2014). Team-based learning represents an even more intense use of small groups to craft the core capability of the organization. As team members become more willing to commit to very high level of effort in their learning they develop systemic way of seeing things, and techniques to solve the problems they encounter in progressing their tasks. In Gallant & Rios, a contention is made about building teams that can perform beyond the capability of even their most talented members. As groups think more about the task at end, the more innovative they can be (Lockheed, 2016).

The Sociotechnical Perspective

The historical background illustrates that the STSD can boast of a long tradition rooted in famous and successful intervention of the Tavistock Institute of Human Relations that solved what could have been a chronic productivity problem in the British pre-WW2 coal industries. The concept of structure was deployed with Adam Smith to define the organizational culture and the efficacies essential in making successful specialists (see Figure 1). In Blau et al (1976), it is postulated that during the fifties and sixties Weber's distinction between the categories of *goal-oriented* behavior and *value-oriented* behavior were still regarded as being of fundamental importance. For example the learner had to develop his skills by observing and taking orders on what to do from the expert. It implied that the division of labor could be viewed as a structure whose rationality was to increase productivity by allowing key actors to become specialists. Blau et al argued that structure was

related to behavior drawn from sociology and economics. The division of labor was the rationale to increase output and innovation became a reality as each divided labor thought about effective ways of doing the job as a means to earn better wages. In much later studies Occelli (2017), argued that the advancements in information communication technologies (ICTs), and mobile computing, has created an information-rich environment where new types of socio-technical systems (STS) can be established. Due to the pervasiveness of ICT in the value creation systems designing and implementing socio-technical systems continue to raise an increasing interest in organizations. They play a crucial role in the improvement of productivity. Occelli suggested that STS were essential in leveraging technology and talent management in competitive environments.

In Beal (2016), the ERP is short for enterprise resource planning. An ERP is a socio-technical system in the sense that it is a tool or know-how deployed to make the job easy in many aspects of organization including human resources or manufacturing management. The enterprise resource planning (ERP) is business process management software that allows an organization to use a system of integrated applications to manage the business and automate many back office functions related to technology, services and human resources. The ERP software integrates all facets of an operation — including product planning, development, manufacturing, sales and marketing — in a single database, application and user interface. It is a socio-technical system that engages management to effectively plan and implement human resources strategy pertaining to recruitment and selection, hiring, training and develop and compensate and retain talent in useful; organization. In Kasemsap (2015), the ERP has emerged as one of the major breakthrough information technologies that can re-shape the manufacturing industry. The ERP is the business application that weaves together all the data within an organization's business processes and associated functional areas. Kasemsap considered the advent of globalization

and the appearance of new forms of organization based on networks of closely cooperating firms, it seems clear that successfully implementing sociotechnical systems such as ERP will take on an increased significance for the survival, growth, and competitiveness of many small and medium-sized enterprises (SMEs).

The Sociotechnical Systems Thinking Proposition

In Miller & Rice (1967), the argument that sociotechnical systems thinking was rooted in industrial democracy and the design of tasks compatible with generic human needs is made. In later research Davis Challenger Jayewardene & Clegg (2014), posited that sociotechnical systems thinking can be viewed as a subset of social theory and philosophy. This way of thinking is particularly relevant in domains such as organizational development which are closely related to knowledge management. Socio-technical systems thinking has predominantly been applied to the domains of new technology and work design in postwar industries. Whilst it has made an impact, Davis et al argue that they need to be valiant, encouraging the approach to evolve and extend its reach. In particular they suggested that the conceptualization of what constituted a system applied in the organization's thinking. To illustrate the claim, Davis et al provided examples of socio-technical perspectives on the management of change and how the approach can be applied to increase in productivity. They argued that there was a positive correlation between sociotechnical systems thinking and reduction in risk resulting in increased yields.

The participative view in sociotechnical systems thinking imply continuous learning and improvement and use of appropriate technology. An assumption can also be made that the key actors in the value chain must perfect their act to remain relevant to the job at hand. In Senge (1990), system thinking encompasses a large and fairly amorphous body of methods, tools, and principles

all oriented to looking at the interrelatedness of forces and seeing them as part of a common process. In Daft (2013), a group of technocrats referred to as skunkworks can meet regularly to solve organizational problems. Their main asset is what they know, and how they coordinate their expertise to create organizational advantages. They examine interrelated forces and see them as part of a common process. Senge asserted that systems thinking follow certain common principles, the nature of which are being discovered and understood by all in the organization. In Mupepi (2017b), the ultimate success or failure of a business in modern society depends on a variety of factors across all levels of the organization. By utilizing dynamic human resource planning techniques and operational teams can lead organization more efficiently to reach desirable goals. Appreciating the configuration and combination necessary in socio-technical systems is pivotal to maintaining and increasing the competitive advantage. For example, the Skunkworks philosophy has been tested successfully at Lockheed Martin Aerospace industry (Lockheed, 2016) and its thesis can be applied to create diffuse and distribute the explicit knowledge required to differentiate the organization in competitive environments successfully. The Skunkworks has continued to be a combination of highly qualified and experienced aeronautical engineers who designed and built one of the most effective jetfighter plane in use today. Daft suggested that the competitive advantage can be created successfully by a people who share the same thinking and mindset. The Skunkworks were able to be innovative in all their deliberation to produce a product that continue to be in demand internationally.

Learning and Improving All the Time

Williams & Hummelbrunner (2010) explore the application of systems ideas to investigate, evaluate, and intervene in complex highly productive organizations. Their proposition serves as a field guide to how sociotechnical systems thinking can

be implemented to take organizations to the next level. Williams & Hummelbrunner describe and analyze organizational learning, and how change can be designed and implemented successfully. Williams & Hummelbrunner places importance on how the sociotechnical systems concept can be put into useful practice that focus on developing system thinking and a shared mental model about how best to do the job at hand.

In Mupepi (2017a), a co-constructed vision of the future is made possible by an organization that can come together to strategize using the same heuristics to solve problems and enable continuous learning and improvement to happen in all facets of organization.

Organizations as Open Systems

In Soliman (2014), System theory provides a first perspective for critical and normative exploration. Systems theory has been deployed successfully to elucidate phenomenon in many fields including organization development cybernetics, and economics, among many others (von Bertalanffy 1969:2). Soliman (2014) posited that the centrality of systems thinking is to view a phenomenon holistically as a set of diverse interacting elements. Mingers & White (2010) suggested that the relationship between the components is more meaningful than investigating each component in isolation. Vancouver (1996), suggested a hierarchical structure of a system enabled accountability and analysis of responsibility. Drawing on this early work Soliman (2014), considered that there were generic characteristics that applied to all open systems such as the importation of energy. In this acquisition all open systems are dependent on their environment for the resources they need to effectively function. Bertalanffy (1934) employs evolutionary biology to explain how the organism amoeba replicates itself to successfully thrive in marshy environments. The amoeba draws energy from the plants, water, sunlight, and air as throughput to replicate itself successfully. The absorbed energy will be transformed by the amoeba open

Table 1. Hierarchy of systems

Level	Characteristics
Framework	Static descriptive (e.g. anatomy of the universe, gene; the patterns of electrons around a nucleus)
Clockwork	Simple & predetermined motion; dynamic, stochastic, equilibria
Control	Self-regulation; Transmission & interpretation of information
Open system	Self-contained, reproduction, throughput of material (e.g. cell and river)
Genetic-Societal	Division of labor, differentiated and mutually dependent parts, Blue prints for growth
Animal	Increased mobility, teleological behavior, Self-awareness, specialized information-receptors
Human	Self-consciousness, self-reflexive quality, ability to produce, absorb, and interpret symbols
Social organization	Value system, Transcription of images
Inspiring	Ultimates, absolutes, and the inescapable unknowables

Source: Boulding, 1956

system to continue to grow. Organization will transform the resources and materials into products or services. In the evolutionary cycle the output of the organisms will be exported back to the environment and thus the amoeba continues to replicate itself faster. Soliman argues that systems are cycles of events characterized by inputs and outputs. The offering of the products or services will generate new resources for organization in order to repeat its transformation process.

Open systems are bound to obtain negative entropy. Entropy as a universal law is the degree of disorder or uncertainty in a system. It states that all organizations will eventually result in disorganization or death. Thus, open systems tend to maximize their ratio of imported and consumed energy to maintain survival (von Bertalanffy 1969:3) Information input, negative feedback, and the coding process are some the characteristics of reproduction in organisms. Open systems not only absorb energy as input but also information. Negative information will provide feedback to the system about its operation and potential need of corrective action.

The Need for Homeostasis

Homeostasis is the property of a system in which a variable is actively regulated to remain very nearly constant. This regulation occurs inside a defined environment. Open systems that are successful in

importing energy to obtain negative entropy are epitomized by a steady state. Negative entropy has been used by biologists as the basis for purpose or direction in life, namely cooperative or moral instincts. However, as the environment of open system will change accordingly. Dynamics homeostasis predicts this process of adjustment (von Bertalanffy 1969:4)

Differentiation

In Barney (1991), firms are viewed as organizations that have different resource endowments that enable them to construct specific competitive advantages over competitors. Resource endowments allow firms to be different which reduces competition and makes it possible to reach new segments of the market. Thus, differentiation is the process of distinguishing the differences of a product or offering from others, to make it more attractive to a particular target market. Barney argued that differentiation is imperative in all open systems to allow specialization to occur and justify their existence and maximize efficiency.

Boulding (1956) provided a dual basis to treat organizations as open systems as well as social systems with the objective to attain a distinctive goal that sets it apart from other social systems. Human beings as open systems were superior among all organism for their capacity to think and reason.

Systems Thinking in Environmental Uncertainty

In Mingers & White (2010), perceived environmental uncertainty has long been employed to describe an objective state of an organization's environment or as a state of an individual's perception about the environment. Attributing certain characteristics to the environment enables organizations to explain and prepare for uncertainty. The adage: forewarned is forearmed makes organizational sense when risk can be planned and anticipated (Milliken 1987).

There are three types of uncertainty and these are: state uncertainty, effect uncertainty, and response uncertainty. State uncertainty is when an individual lacks information about the nature of the environment on how environmental events, changes, or set of changes will affect the particular organization. With response uncertainty an individual experiences an inability to predict accurately what the organization's response options are in accomplishing desired outcomes. Subsequently it is the type of information an individual lacks that determines which type of perceived environmental uncertainty s/he experiences. State uncertainty is conceptually the closest to using the term environmental uncertainty to describe the state of an organization's environment (Milliken, 1987:121).

Feedback

Argyris (1990) postulated about double loop learning and how organizations could improve productivity by giving each other constructive feedback. Argyris referred to this phenomenon about learning as the ladder of inference. Argyris suggested that the organization's ability to achieve desirable outcomes was truly eroded by feelings that generated ideas such as: our beliefs are the only truth, our beliefs are based on real data, or the data we select are the real data. Argyris & Schon (1978), suggested that double loop learning provided the learner with appropriate feedback

which enabled the learner to draw useful lessons to perfect his act. Double-loop learning occurred when error an error was detected and corrected in ways that involved the modification of an organization's underlying norms, policies and objectives.

RECOMMENDATIONS

Learning to see the organization systematically is something intangible as deeply set attitudes found in many companies. There are four levels of a systems view. The first is made up of the organization's notable events such as success stories. How the team met the sales targets in a given period of time can be employed to remind current employees that targets can be achieved if there is teamwork (see Figure 2).

The second perspective concerns patterns of behavior (see Figure 2). Drawing lessons from trends of the system over time is important in charting the change discourse. Instead of listing isolated historical events forecasting can be deployed to chart the future with some degree of accuracy.

The third is about the systemic structure. This activity examines the interrelatedness of the events to the system and how the parts are connected to make the whole *holon*. The group can discuss the key interrelationships between these parts factors and events to understand if there are any causal relationships (see Figure 2).

The fourth part is the mental model. The mental models are tacit, they relate to experience. Two people with different experiences can relate to the same object differently. Mental models shape how people behave. The core task of the fourth part is to talk about the job candidly. There are mental models that should not be sustained. For example managers may believe that poor quality is a sabotage by the hourly paid workers. What needs to be encouraged is the analysis of the system with its other parts to understand the causes of the problem of poor quality (see Figure 2). Mental models are also critical in designing and implementation of successful organizational training and development programs.

Figure 2. Organizational interrelated factors impact the core competency

Sociotechnical Systems Thinking Is Good for Business

In Beal (2016), the last couple of years have unleashed forces which are fundamentally shifting behavior in the use of sociotechnical systems such as the ERP. The industry has new and continuing trends such as the development of the following software:

- **Mobile ERP:** The business community want real-time access to information, regardless of where they are. It is expected that businesses will embrace mobile ERP for the reports, dashboards and to conduct key business processes.
- **Cloud ERP:** The cloud has been advancing steadily into the enterprise for some time, but many ERP users have been reluctant to place data cloud. Those reservations have gradually been evaporating, however, as the advantages of the cloud become apparent.
- **Social ERP:** There has been much hype around social media and how important

– or not -- it is to add to ERP systems. Certainly, vendors have been quick to seize the initiative, adding social media packages to their ERP systems with much fanfare. But some wonder if there is really much gain to be had by integrating social media with ERP.

- **Two-Tier ERP:** Enterprises once attempted to build an all-encompassing ERP system to take care of every aspect of organizational systems. But some expensive failures have gradually brought about a change in strategy – adopting two tiers of ERP (Beal, 2016).

LIMITATION

Sociotechnical systems thinking approach in management can be limited to many aspects associated with teams. Creating a shared mindset among groups of workers may require building team work. In this process effectiveness can be enhanced when the group does the similar jobs where teamwork can become meaningful. Creat-

ing a shared mindset can require a lengthy period of time. People need time to reflect and build effective interpersonal communications among themselves. Failure to achieve a sociotechnical systems thinking can result in frustration among members of the organization.

FUTURE RESEARCH DIRECTIONS

Future research should endeavor to study more contextual factors such as organizational culture useful in socio-technical organization systems (see Mupepi 2017a). Surveys distributed to customers can be analyzed to produce performance metrics necessary in increasing output (see Mupepi (2017b). The same data can be analyzed to design and implement exploitable databases which be interpreted to understand the responsiveness of customers and behavior in competitive environments.

CONCLUSION

Organizational learning undergirds sociotechnical system thinking. Constructive feedback is essential in continuous learning and improvement. Feedback is a common mental pathway of increasing abstraction and can often mislead individuals to misguided beliefs such as the sabotage of quality by the hourly paid workers.

KEY TERMS AND DEFINITIONS

Algorithm: An algorithm is a self-contained step-by-step set of procedures applied in solving mathematical or industrial problems.

Differentiation: The process of making products or organization different from others in competition.

Holon: Adapted from Hebrew implying a self-containing part which is part of a larger system.

Skunkworks: A project typically developed by a small and loosely structured group of people who research and develop a project primarily for the sake of innovation.

Systems Thinking: Systems thinking involves the use of various techniques to study systems of many kinds.

Ubiquitous: Omnipresence or ubiquity is the property of being present everywhere.

Value Creation System: A value creation system is a production perspective that describes social and technical resources employed to produce goods and services demanded by customers.

The Application of Crowdsourced Processes in a Business Environment

B**Katarzyna Kopeć***Tischner European University, Poland***Anna Szopa***Jagiellonian University, Poland*

INTRODUCTION

Globalization is creating tremendous opportunities as well as challenges for businesses. There can be observed increasing emphasis on maximizing creativity, human capital and problem solving. Companies are more likely to be innovative and shape ideas as well as to create attractive propositions for users or customers (Cox, 2005). On the other hand, consumers are becoming more like external employees who take over specific parts of a design process, whereby this process finally remains under the control of a company (Kleemann, Voß, & Rieder, 2008). The recent shift towards a polycentric perception of business making requires the involvement of stakeholders in an organization's management. This is a starting point for looking at the idea of crowdsourcing as an innovative business model. Crowd-based business models enable organizations to harness the collective energy, through different processes, companies gather a large population by inviting users to create value (Kohler 2015). The inclusion of stakeholders in the process of developing new products or services forms a general foundation of this notion. Entrepreneurs take advantage of crowdsourcing ventures due to the delegation of tasks to stakeholders in the form of an open call.

Organizations rely on crowds for different reasons, e.g. in order to create content, evaluate, create or to solve problems. The article's aim is to present crowdsourcing as innovative business model in the context of evolving consumer society based

on the OpenIDEO case. In addition it highlights the pros and cons of crowdsourcing as well as prospective research directions that might clarify some unidentified aspects of crowdsourcing.

BACKGROUND

Technological advance including Internet's development of the late 1990s and thus the wide recognition of web-dependent participatory culture in the 2000s (Brabham, 2013) has resulted in the inclusion of consumers into the process of creating new ideas also for business. In consequence, this link between enterprises and the groups of consumers has become more and more evident.

The idea of outsourcing a business task to the web-based community is a relatively recent invention, although it shows a close relationship with other deep-rooted concepts. The literature points out the catalogue of crowdsourcing-related notions such as prosumerism (Toffler, 1980), user-innovation (Hippel, 1988), open-innovation (Chesbrough, 2003), co-creation (Prahalad & Ramaswamy, 2004). These terms, however, overlap with crowdsourcing. The notion of crowdsourcing has experienced a great success in a variety of areas. Its evidence are blogs (e.g. www.crowdsourcing.com by Howe; <http://dbrabham.wordpress.com> by Brabham; <http://www.crowdsourcing-blog.org> by Estellés-Arolas), books (Howe, 2006, 2008; Tapscott & Williams, 2006, 2013; Surowiecki, 2004) including academic contributions (Brab-

ham, 2013; Chanal & Caron-Fasan, 2008; Pénin & Burger-Helmchen, 2011; Vuković, 2009; Estellés-Arolas & González-Ladrón-de-Guevara, 2012).

The term crowdsourcing (which is a blend of *crowd* and *outsourcing*) was coined and popularized by Jeff Howe in the 2006 *Wired* article (Howe, 2006). It is a real challenge to define clearly the idea of crowdsourcing as it is not a coherent term. The term has developed on the intersection of various disciplines, and thus a variety of approaches overlap here. It is also a marketing slogan of a rapidly growing recognition. Thus, scholar discourse mixes with popular media discourse which leads to “unkempt theory and practical crowdsourcing applications with shaky foundations” (Brabham, 2013, p. 6).

Howe (2010) states that “crowdsourcing is the act of taking a job traditionally performed by a designated agent (usually an employee) and outsourcing it to an undefined, generally large group of people in the form of an open call.”

Estellés-Arolas and González-Ladrón-de-Guevara (2012) in their article surveyed a vast number of existing crowdsourcing interpretations. They succeeded to develop an integrated definition of crowdsourcing based on 40 definitions identified in the literature so far. “Crowdsourcing is a type of participative online activity in which an individual, an institution, a non-profit organization, or company proposes to a group of individuals of varying knowledge, heterogeneity, and number, via a flexible open call, the voluntary undertaking of a task. The undertaking of the task, of variable complexity and modularity, and in which the crowd should participate bringing their work, money, knowledge and/or experience, always entails mutual benefit” (pp. 9-10). This definition points out the following key elements of crowdsourcing: an organization that has a task to be carried out, a crowd ready to complete a task voluntarily, an online environment enabling an organization to work with the crowd on a task and mutual benefits for both parties (Brabham, 2013).

Advantages and Disadvantages of the Crowdsourcing Process

Grün and Brunner (2002) state that one of key advantages for companies to announce crowdsourcing initiatives is cost reduction. It is possible when a business task can be outsourced to the customer via the Internet. To the pros of crowdsourcing belongs also the inclusion of users into the quality improvement and efficient use of resources. The crowdworkers can be co-designers, co-producers, testers, evaluators, and thus they can participate in product innovation. Reichwald and Piller (2006) see further advantages to involve customers in the value creation process that can be also adopted in the case of crowdsourcing: saving time for new product enhancement, wider acceptance of new products among customers, and strengthening consumers’ individual assessment of the new product’s originality. Kleemann, Voß and Rieder (2008) notice that companies encourage users to take part in crowdsourcing initiatives by presenting the distinctive, but intangible quality of the open content culture which emphasizes the perception of enterprises as community-orientated and creative entities. This is consistent with the domains in which crowdsourcing is commonly used: configuration, design and testing of products, innovation, and problem solution.

The users take part in crowdsourcing to develop one’s creative skills, network with other creative professionals, share with others or develop a portfolio for employment in future. Other crowdworkers are driven by the challenge to solve a puzzle, they want to contribute to a large project of common interest or they are lured by financial reward (which is the most frequent one). (Brabham, 2008a, 2010, 2013; Lakhani, Jeppesen, Lohse, & Panetta, 2007; Acar & van den Ende, 2011; Rogstadius, Kostakos, Kittur, Smus, Laredo, & Vuković, 2011).

Interestingly, Reichwald and Piller (2006) discovered that consumers actively participating

in product innovation are also driven by dissatisfaction with current solutions. They expect to support a company in product improvement and innovation.

It is important to remember that crowdsourcing communities are a subsection of broader online communities. Their typical activity is to respond to open calls posted by enterprises. In general, crowdworkers are members of a broader concept of participatory culture and believe their contributions matter (Jenkins, 2009).

The literature reveals also legal and ethical pitfalls that crowdsourcing may face. Felstiner (2010) found out that the legislative framework of crowdsourcing labor model is based on existing labor laws which does not address a variety of employment-related issues (status of a crowdworker, issue of control, employee's working equipment). It is almost impossible to flexibly revise the law due to the specific features of crowdwork – it is carried out online (in cyberspace), by anonymous crowdworkers, and governed by obligatory participation agreements (usually in the form of a pop-up window which informs that users are obligated to agree to the terms and conditions before using the software). Felstiner analyses the example of Amazon's Mechanical Turk, where its members can accomplish a series of "human intelligence tasks" (HITS) for small monetary rewards paid by the "Requester." In this crowdsourcing form workers become unquestionably low wages (an average crowdworker works eight hours per week on Amazon's Mechanical Turk for below \$2 per hour, for example a crowdworker for writing only a short definition of a new term may earn \$0.03 (Ross, Zaldivar, Irani, & Tomlinson, 2009; Ipeirotis, 2010). Brabham (2008b) states that the intellectual labor of the crowd is worth more than winning solutions are paid (in the literature referred to as "digital sweatshop," "virtual sweatshop" or "cyber-sweatshop" by Scholtz (2013). Wolfson and Lease (2011) highlight a subsequent legal problem of crowdsourcing initiatives, that is, copyright ownership and patent inventorship (e.g. joint inventorship) since it is rather difficult

to control creative works delivered by crowds. Another crowdsourcing-related risk is consumer data security as enterprises can attempt to reveal data about their crowdworkers to external parties to support research and development. In addition, crowdsourcing initiatives raise ethical concerns like substituting company's own employees with lower-wage crowdworkers what shows the exploitative nature of crowdsourcing (digital sweatshop, slave labor) for the enterprise's benefits (Harris, 2011).

CROWDSOURCING-BASED BUSINESS MODEL

In essence, a business model clarifies the process of how an organization creates and captures value and helps understand how a firm is embedded in and interacts with the surrounding ecosystem (Teece, 2010). The term crowdsourcing accentuates a novel business model to solve problems by leveraging the "collective intelligence" (Lévy, 1997) of crowds in which a major communication platform is based on the web. Crowdsourcing in the context of the new type of consumer can be explained through crowd wisdom, communicative planning and collective intelligence as groups are often smarter than the smartest people in them (Surowiecki, 2004).

To put it simply, an organization (crowdsourcer) announces a problem online, and individual members of an online community (crowdworkers) voluntarily submit their proposals to face an issue and to put forward a solution of a problem addressed. Eventually, an organization chooses one or the best-tailored solution for which a crowdworker gets a bounty (e.g. financial award, self-esteem, economic recognition, social recognition). What is more, an organization can use the right to employ this idea in its business activity. Schenk and Guittard (2009) point at this distinctive feature of crowdsourcing saying that a crowdsourcer takes advantage of going for an option that best meets his/her expectations, what means that he/she pays

for a product after its acceptance. In crowdsourcing business model the new consumer type is providing services usually for free, however, the capacities that he/she possesses are valuable economic assets. He/she takes part in the production process and is perceived as value-adding worker. The crowdworker is systematically integrated into corporate structures, and his/her activities are supervised by project managers as if he/she was an employee.

The intensity of involving groups of customers into an enterprise's operation is in crowdsourcing much more advanced than in any previous business models. Brabham (2013), as one of very few scholars, very clearly draws the line between activities that belong to crowdsourcing and those that cannot be included into this concept. It is of great importance as the popular media definitions which are situated outside the scholar literature blend all tendencies into one term crowdsourcing. Brabham points out the following features that differentiate crowdsourcing from similar creativity-based processes: top-down management, shared process of bottom-up creativity, locus of control with regards to the creation process between an organization and the public. It is important to notice that the concept of open source (e.g. Linux) and commons-based peer production (e.g. Wikipedia) are by Brabham (2013) excluded to be perceived as crowdsourcing (no top-down management, locus of control resides among the users).

Crowdsourcing Taxonomy

There are few approaches to classify crowdsourcing, including one most transparent taxonomy by Brabham (2013) presenting four dominant crowdsourcing types in business operation:

1. **Knowledge Discovery:** This crowdsourcing type is similar to commons-based peer production (e.g. Wikipedia), where users create online content. In this crowdsourcing case the organization manages the process of knowledge discovery (what information
2. **Broadcast Search Approach:** The focus is put here on searching scientific solutions by selected problem-solvers. Example: OpenIDEO – a platform where individuals work out challenges devised by OpenIDEO customers (for details see case study below). Based on a statistical analysis Lakhani et al. (2007) found out that solvers were able to solve 29% of the problems of the seekers (large companies with R&D departments) that had remained unsolved before. In the broadcast search approach, financial remuneration is commonly designed for problem solvers whose solution wins (though financial incentive is in this case not the only motivation to participate in crowdsourcing) and the intellectual property belongs to a seeker.
3. **Peer-Vetted Creative Production Approach:** The creation process is open to online community and finally the best option is selected. This approach can be applied in the matters of user preferences, also one's business can be based on crowdsourcing strategy. Example: Threadless.com, online company selling t-shirts based on design provided by artists (artists who provide winning designs are presented cash bounty). The best designs (of the month, of the week) to be produced are selected in a voting process.
4. **Distributed Human Intelligence Tasking:** Appropriate approach when the data is available but the problem includes data processing which can be split into small tasks done by the humans only. It is the least creative task, and financial reward is often a stimulus to

is needed, its objective, ways to collect this knowledge). Example: SeeClickFix, a web and phone application that allows citizens to report non-emergency problems (potholes, graffiti etc.) in their local community. City governments use SeeClickFix as the mechanism to better understand issues facing the community and to better allocate resources to fix problems.

participate. Example: Amazon Mechanical Turk. It is an online platform that essentially coordinates sets of effortless jobs which cannot be provided by computers as they require human intelligence. In this model “requesters” (employers) solicit jobs (usually microtasks) like tagging images, responding surveys, rewriting texts, transcribing audio, conducting Internet research etc. to be accomplished by “providers” (workers).

In general, crowdsourcing has been made possible thanks to the evolution of information and communication technology which supports innovation and development of enterprises. There are several ways enterprises can apply crowdsourcing strategies. Aitamurto, Leiponen and Tee (2011) classify internal crowdsourcing initiatives (e.g. IBM innovation jams which take place internally within the IBM various divisions), external crowdsourcing initiatives (e.g. LEGO Group’s LUGNET or DELL’s IdeaStorm that enables users to publish their product-related ideas or product improvements) as well as collaboration initiatives that are outsourced to companies specializing in crowdsourcing innovation problems to the public (e.g. InnoCentive.com). However, the crowdsourcing application is not restricted only to companies. They also can be implemented by non-governmental organizations that also take advantage of crowdsourcing strategy (e.g. the US Federal Transit Administration project which involved neighborhood’s residents to design a better functioning bus stop in Salt Lake City, Utah).

OpenIDEO’s Application of Collective Problem Solving Model

OpenIDEO is an open innovation platform existing within the IDEO company structure. IDEO is a design company located primarily in Palo Alto, California. It was established in 1991 from existing design firm (Taylor, 2005). This success company is ranked as one of the most innovative

companies in the world by business leaders in a global survey by Boston Consulting Group, (IDEO, 2015).

The crowdsourcing process in OpenIDEO starts with defining problem, which then is divided into several themes published on the website. Defined problem is divided into four phases. At the first phase – Inspiration – the crowd educates itself on the larger question, both informing and inspiring. Suggestions are voted, the so-called applauding process elevates the highest voted submissions to the user in the next phase. Then at the Concepting stage all solutions are collected to the larger problem. At this stage using the crowd voting results, the company cooperates with the Challenge sponsor to narrow the list of concepts to twenty. In the third phase, that is, Evaluation, the crowd again submits ideas as comments to refine and expand the winning concepts. Furthermore, each comment stands also a subject to the applauding process and motivates the author of the concept to acknowledge and include comments that receive frequent crowd approval. Then the crowd votes on the refined concepts, and OpenIDEO once again cooperates with the Challenge sponsor to select a final list of winning concepts that the sponsor implements. Presented process broadly comprises company’s problem-solving platform, which repeats the crowdsourcing process in each phase. At the final stage, Realisation, discussed project is implemented into real life. OpenIDEO also profits from having multiple solvers scattered across the landscape, but in addition allows them to exchange information and construct solutions together. (OpenIDEO, 2015). The main idea of presented crowdsourcing process is to allow the crowd to create solutions in each stage, and at the same time consequently making progress toward creating a comprehensive solution - its approach is to populate the same landscape with a small number of contributors and endorse initial solutions’ improvement over repeated iterations, each iteration bringing it closer to the optimal explanation.

FUTURE RESEARCH DIRECTIONS

The vision of possible crowd-workplace which substitutes a traditional workplace is hardly discussed in the literature. Paid crowd work is a great chance to enhance “productivity, social mobility, and the global economy by engaging a geographically distributed workforce to complete complex tasks on demand and at scale.” (Kittur et al., 2013, p. 1301). It is important to stress some aspects related to the crowdsourcing process in an enterprise’s operation which should be explored further. Among them we can mention internal and external factors that exert influence on the way enterprises manage their resources. Crowdsourcing business model changes organizational structure, relationships between employer and employee, quality control etc. And this is why there will be a need to tackle with the following questions of holistic nature: Will crowdsourcing model affect employee’s motivation to work? Will traditional employees be replaced by web-based crowdworkers?

There are also questions of functional nature which are focused on crowdsourcing as business model to be implemented in an enterprise’s operation: Can crowdsourcing be formalized (career levels, quality, task assigning, crowdworkers’ training)? How to manage synchronous collaboration between a crowdsourcer and a crowdworker? How to manage online work tasks? How to attract efficient crowdworkers? How to manage shared resources?

CONCLUSION

Pierre Lévy (1997) claims that since “no one knows everything, everyone knows something,[and] all knowledge resides in humanity” (pp. 13-14). His statement reflects the main idea of crowdsourcing process. Crowdsourcing means that anyone with Internet access can accomplish a task provided

by a company worldwide. Thus, crowdsourcing gives companies a great chance to distribute tasks on demand to an international group of crowdworkers. It is a great opportunity to internalize consumers’ thoughts.

This article describes crowdsourcing as a business model that can be applied by enterprises intending to empower consumers (prosumers). Enterprises create innovations in order to gain competitive advantage in the traditional, as well as in cyber-marketplace. In this context, crowdsourcing is an original instrument for advancing products, developing online services, and fostering online communication with users. What is more, crowdsourcing links an open creation process with conventionally managed top-down process in which prosumers play a significant role.

They are integrated into the corporate value creation by engaging them (their competencies and knowledge) to develop products/services to meet consumers’ needs. The emergence of crowdsourcing-based business models is driven by technology, active users, and the move towards open innovation.

Among the advantages of crowdsourcing we can indicate: cost effectiveness (crowdsourcing basically reduces the costs of hiring and dismissal of employees), the opportunity to involve crowdworkers in a business activity on demand, recruitment flexibility. On the other hand, it is important to accentuate legal and ethical risks emerging from crowdsourcing practice (lack of regulations related to online labor, “digital sweatshops”). Paid crowdwork is perceived as ethically controversial, however, it is the crowdsourcing option which gains great popularity since it gives the opportunity to labor mobility.

The suggestions presented above lead to the conclusion that companies have much to learn from crowds. Identifying how to harness the power of crowds is the essential step for companies to differentiate themselves in the marketplace and sustain their competitive edge.

KEY TERMS AND DEFINITIONS

Broadcast Search Approach: A type of crowdsourcing which focuses on scientific solutions by a group of selected problem-solvers (e.g. InnoCentive – a platform where scholars work out challenges devised by its customers).

Collective Intelligence: Shared or group intelligence that emerges from the collaboration, collective efforts, and competition of many individuals and appears in consensus decision making.

Crowd Wisdom: The process of taking into account the collective opinion of a group of individuals rather than a single expert.

Crowdsourcing: A business model in which one party (an individual, a company, a NGO, a public institution) solicits a group of individuals for solving a task via the Internet.

Distributed Human Intelligence Tasking: A type of crowdsourcing in which the core issue is data processing by the humans only (e.g. Amazon Mechanical Turk, an online platform coordinating jobs which can be provided by Internet users).

Knowledge Discovery: A type of crowdsourcing which is based on creating online content by users, however, this process of knowledge discovery is managed by an organization (e.g. SeeClickFix, the US website on which people can report non-emergency problems in their local community via the Internet or a mobile phone application).

Peer-Vetted Creative Production Approach: A type of crowdsourcing in which the creation process is open to web users. This web-based community work out solutions that live up to the expectations of an organization. Finally the best option is selected (e.g. Threadless.com, online company selling t-shirts based on design provided by artists. The best designs are chosen in a voting process).

Prosumer: Proactive consumer; takes an active role in creating a product or service.

Architecture as a Tool to Solve Business Planning Problems

B

James McKee

Independent Researcher, Australia

INTRODUCTION

Architecture can give systematic structure to problem investigation, solution development and formality of presentation to the solution plan. An architectural reference model will allow the planners guidance in their investigations and in their development of the plan. An architectural blueprint of the solution will allow implementers to better understand the intentions of the planners.

Architecture is essential for any large building or urban planning proposal (not the aesthetics of the design but the structural design – how things fit together), why should this architectural discipline not help in designing solutions for other types of large scale problems? The architecture discipline would not only aid the development of the solution but allow the project plan to become a better communication document. There is therefore a need for a generalized discussion on the basic architectural principles that can guide the development of architectures for different problem areas.

A key argument for architecture versus design is that design solves the functional requirements of the specification whereas architecture is in *addition*, about the long term sustainability of the solution and in the process takes into account more environmental factors (market place, competitors, etc.). A definition of IS architecture given by Bass, Clements and Kazman (1998) allows a clear distinction between architecture and design. They write that architecture begins the task of envisioning the central function of a system looking for those influences that persist beyond the lifetime of the system, whereas design is just about ensuring the system will function as expected.

In other words, architecture is concerned with a need to explore beyond the immediate description of functionality and is required to also stretch the boundaries, looking at any environmental factors that surround the objective. The architecture gives much more knowledge about the structure and integration of the entire system being described. The sustainability is due to lower cost and risk associated with development changes because of that knowledge.

Architecture provides a systematic examination of the entire enterprise from a summary overview at the top level of abstraction with navigating links to all the component parts and their definition at descending levels of abstraction and with descriptions of any interactions between component parts. This blueprint, if correctly done, can be a powerful management tool for determining where efficiencies can be made and choosing effective strategic directions.

However before beginning the analysis of the organisation, a set of architectural principles need to be adopted to guide the analysis and to develop a reference model of the organisation's business architecture for use in presenting the analysis results in the architectural format for any specific enterprise and this will be discussed in the section headed architecture as a solutions tool.

BACKGROUND: CONCEPT OF ARCHITECTURE IN COMMERCE

Architecture is often considered as just the aesthetics of the building design but there are entire undergraduate and post graduate courses

DOI: 10.4018/978-1-5225-2255-3.ch050

on building architecture that go beyond just the classic proportions for a building but detail the formulas and tables on the structural loads for foundations and support walls etc. A great many technical issues are pre-solved for use in the design and development of a new building.

The idea of architecture has now been extended to the area of information technology although this is fairly recent say within the last 30 years; two of the most influential authors in the early years were Brancheau, and Martin. Brancheau and Wetherbie wrote “an information architecture is a high level map of the information requirements of an organisation” (1986), however I believe the use of the term ‘map’ diminishes the amount of structure inherent in an architecture. Martin in 1990 drove the emphasis for *information* with his books on Information Engineering and his depiction of an architecture to describe the enterprise. There are various descriptions of enterprise architecture used by the IT profession, a very detailed description is given on the web site for TOGAF (2013) and Koontz (2000) gives a very clear layout of the different levels in the enterprise architecture. All these descriptions of enterprise architecture are essentially intended to improve the design of IT systems to align the information systems better with the business operation and strategic development.

Harmon (2008, 2004) has also stated this pre-occupation of definitions for “enterprise architecture” to be focused on the application of IT resources. Harmon (2004) also shows a detailed description of the hierarchy of levels in enterprise architecture, but in his view of the enterprise the focus is on the business processes and that business process management is a key component of the “enterprise architecture”.

Following the emphasis on business processes there was a focus on creating standard processes by the management consulting and software development world and the concept of service oriented architectures (SOA) was developed. I believe the emphasis should be with the requirement to determine the structure of the enterprise - including

what product suits the available market at what price point and what style of distribution to use etc., - before reviewing the processes required.

An information architecture has been proposed by McKee for presentation of the strategic plan, to pick up after the creative determination of the strategic objectives and to focus on the implementation plan. The architecture included determining the planning information components, their interaction and the overall structure of the plan and a reference model was developed for the presentation of this information, which is explained in more detail in a later section (McKee, 2013).

There are now many discussions about the need for business architecture; a white paper entitled “The Evolution of Business Architecture” was written by a business consultant (Cochlin, 2012). Cochlin defines business architecture as: “Transforming corporate strategy into business designs, structures and aligned delivery capabilities that enable corporations to increase market share, return on investment and agility in the face of change, whilst at the same time reducing risk”. However the use of architectural design in the business world needs a lot more definition of frameworks and reference models than is currently available. A comment from some management consultants is to say that it is a specialist function to interpret the business processes and requirements into an architecture and it may not be appropriate to have generic models available for the business person to use themselves. Surely the senior business managers are in the best position to determine and then describe the functions and structure of the organisation, however they do need some examples and reference models to guide them.

One definition of enterprise architecture is that it is “a conceptual blueprint that defines the structure and operation of an organisation. The intent of an enterprise architecture is to determine how an organisation can most effectively achieve its current and future objectives. Purported advantages of having an enterprise architecture include “improved decision making, improved adaptability to changing demands or market conditions, elimi-

nating redundant processes, optimization of the use of organisational assets and minimization of employee turnover” (Rouse, 2007).

There is an increasing number of books and articles now available with business architecture as the primary focus, many are being written by consultants rather than academics. A definition of business architecture is given by Ulrich & Kuehn “business architecture is a blueprint of the enterprise that provides a common understanding of the organization and is used to align strategic objectives and tactical demands [quoting the Business Architecture Guild]. It is an abstract set of standardized perspectives that represent a given business ecosystem. The foundational perspectives include the following core “domain” categories:

- What a business does (capability)
- The vocabulary it uses (information)
- How a business is organized (organization)
- How a business delivers value to key stakeholders (value stream)” (Ulrich & Kuehn, 2015).

However the discussion of what constitutes a business architecture is very broad and diffuse from many business consultants and minimal direction from academia creating a lack of common definitions and frameworks for business managers to refer to and use.

ARCHITECTURE USE IN COMMERCE IS LIMITED

Zachman was very concerned that “[t]he credibility of IS is in a steep decline.” And that “[t]he issues of quality, timeliness and change are the conditions that are forcing us to face up to the issues of Enterprise Architecture” (Zachman, 1996, p.1). If these issues were thought to be very relevant to the development of effective IT systems, how much more relevant can they be to developing a modern effective business organisation and in fact one could extrapolate to saying any large complex operation.

James as the Asia-Pacific Architecture Research Director for Gartner (a company of IT industry analysts), and in an article for the newspaper *The Australian* writes about the need for a business to respond ever faster to the changing environment, and this diversity must be managed effectively to get good business results. That Enterprise architecture is important is largely because there are more applications today than ever before. And those applications are managing more data on a diverse range of platforms, written in many languages and running in a variety of environments and this diversity can be chaotic to manage (James, 2001). A similar argument can be made for the modern global business competing worldwide in rapidly changing environments (political and marketplace).

James is clear that for business success there needs to understanding of enterprise architecture: “Within the control of the enterprise are the technologies that are employed (IT architecture), the business processes, functions and information (information architecture) that embody the organisation and the integration infrastructure (the city plan)” (James, 2001).

Unfortunately the emphasis in these quotes and other similar writings about enterprise architecture is on developing a better IT system, rather than understanding the key operational structures and dependent relationships of the business organisation. Even though the definitions for enterprise architecture do include defining the business and strategic planning functions, they seem to be only there as an afterthought to support the IT development. There needs to be an approach that starts with the business focus.

Issues

There is quite a large body of material that now help explain and define information technology architectures which gives the information systems designer useful tools to aid the analysis and the design of new systems. The architectures gives the designer, the analyst and the programmer a common view of the problem and its solution,

this reduces uncertainty and aids communication and reduces problems with the reliability of the product.

However there is still not a great deal of undergraduate offerings in the architecture fields (IT or business), and there should be discussions at least on how effective or how well they describe and define their problem area. Another issue is that because the focus is of the business world and the profit to be made, several researchers in the area of architectures for information technology are now management consultants to the industry and no longer write academic research papers.

There is very detailed specifications from TOGAF and others for 'Enterprise Architecture' which is purported to cover everything from the Strategic Plan, Business Architecture to the IT System. But the reality is the focus of 'Enterprise Architecture' is very much on what is required to build the IT system for the organisation. This paper reviews the background to the use of architecture in commerce and the discussion on 'Enterprise Architecture' and the limitations associated and will then propose the way architecture can be used for problem evaluation and solution development with the focus on business planning.

Where are the generic reference models and frameworks for use in business architecture? A first response is to indicate that the Zachman framework and the TOGAF information on architectures provide this requirement. Grigoriu argues that the Zachman's matrix describes the various cells of the framework but does not explain how to model them and so is of very limited in help with building the enterprise architecture. He also criticizes the TOGAF website of architectural information as being primarily concerned with IT architecture not with the business architecture and has neither information navigation nor an integrated view of the enterprise (Grigoriu, 2013), Grigoriu is an executive consultant in Enterprise Strategy and Architecture.

Controversies

Many heads of organisations would argue that their business is too complex or too diverse or too changeable to spend the necessary time developing an architecture for their operation and they would question where the return on investment might come from.

Several authors including (Grigoriou, 2011; Sereff, 2012; and Ross Weil and Robertson, 2006) are now writing about business architecture as a fundamental part of enterprise architecture. Enterprise architecture (EA) was first developed to enable the IT world to better understand the business enterprise and therefore create IT systems better aligned to the business needs. Unfortunately there is still a leaning toward IT with the enterprise architecture definitions; Ross, Weill and Robertson make a determined effort to avoid this trap and rail against "traditional IT architecture as too remote from reality of business" Grigoriu also reported his view that many speakers thought the enterprise architects should be more business oriented and that many did not have a clear definition of what Enterprise Architecture is. This is perhaps a reflection that the subject of architecture is much underrepresented in University courses, how many MBA's have a component on the topic of architecture?

One area of architecture that is getting some prominent exposure is that of business intelligence (BI) architecture, one major player is IBM and their Cognos subsidiary. Cognos has of course been in the area of developing software for management and executive information systems (MIS and EIS) for a long time along with many other software companies. These packages allow non-programmers to ask (English like) questions of the company databases (IBM-Cognos, 2011).

A concern is that looking into the data base for answers to your management questions about whether strategic directions are being achieved is

the wrong end of the planning and development cycle. The performance questions need to be determined at the time of creating the strategic objectives with the actions necessary to achieve them; maybe the performance measurements can then be built into the information system and the results fed into the data base. Therefore the business management questions and strategy formulation should be at the beginning of the planning cycle together with the performance measures, rather than examining what has been collected via standard operational transactions.

Problems

It can be justifiably argued that every organisation is different; the argument might then go on to say there are few common denominators of operation across organisations that could have an architecture defined. A significant problem with research on the subject of defining an architecture, is the difficulty associated with proving the effectiveness or usefulness of the architecture because of the long term and the confidential nature of the subject, however the normative model does provide a research option (Routio, 2005). There is a multitude of definitions for enterprise architectures but there is a lack of models & frameworks that provide a cohesive structured format to define a business.

The problems of definitions and frameworks can be seen very specifically in the area of the business model which is deemed by many to be of critical importance “great business models can reshape industries and drive spectacular growth” (Johnson, Christensen & Kagerman, 2008) but Linder & Cantrell (2000) say that “everyone talks about business models but 99% have no clear framework for describing their model” (2000, p.2). The lack of motivation in this respect may well be driven by the concern over the lack of a common definition for the business model, Sorensen promotes the combination of business model and business plan states that “there are no established definitions of business models in the literature today” (Sorensen, 2012, p.155).

Reviewing the definitions for the business model there is ambiguity over the use of the term ‘value’ with conflict between value for the customer and value to the organisation. There is also discussion whether strategy fits in the model or not, and if the whole of the organisation operation is covered by the model, which would make the model too complex to be updated on a regular basis (McKee, 2015).

As indicated above the business model and the strategic plan are often described as part of the enterprise architecture along with all the information of business processes and other business resources making the total amount of information very unwieldy to use as a communication tool as a regular management function.

There is often a lack of effective communication in organisations, particularly across the management silos and is of particular concern when attempting a coordinated approach to strategic objectives that cross management boundaries, (large organisations and multinational organisations are especially vulnerable).

Planning sessions have a potential danger when participants lack objective consideration of all the factual information about the problem area under discussion. They can be prejudiced by subjective misdirection on critical information by inappropriate cues. Rea and Kerzner (1997) refer to errors in judgment where people have a tendency to remember only those things that confirm existing belief rather than examine and analyse more accurate and objective material. Similarly Alter draws attention to eight common decision making flaws and advocates the use of more objective data that can be drawn from the information systems. The same can be said of any management decisions being made without the support of coherent structured information about the organisation which should be contained and presented via a well-designed architecture.

The enterprise architecture is supposed to contain both the business architecture and the IT architecture, however in enterprise architecture models they both appear as independent compo-

nents of the enterprise architecture. In these models there are no relationship mechanisms or dependencies shown between the two architectures and therefore no impact statements to say the amount of effect of the IT component on each of the of the business components. It is well understood today that an effective software system package that is well aligned to the business processes of a particular department and carefully implemented can drive up the profitability of that department, and this relationship should be measured with the degree of impact well understood.

Authors Harmon and Grigoriou complain that many descriptions of enterprise architectures are not able to be used to model the enterprise effectively. However unless the architecture includes descriptions of components with rationales, interactions and relations defined, then the architecture will not allow effective modelling and will not be sustainable in changing conditions.

ARCHITECTURE AS A SOLUTIONS TOOL

Minztberg suggests an important function of a plan is to be the communications media; “plans clearly serve in two capacities, or roles. They are media for communication and devices for control”. He writes that the concept of coordination is “to ensure that everyone in the organisation pulls in the same direction, which may be facilitated by specifying that direction as precisely as possible”

(1994, p. 351-352). It is necessary to have a solution document that has a systematically structured format to give implementers the clear instructions for what is required. If you start with an ill-defined process it is likely that the resulting solution is going to be sub optimal.

An architectural blueprint of the organisation would go a long way to ensuring that all the staff are on the same page and by including the strategic plan within the enterprise architecture then it would ensure development of the organisation would be as effective as possible. The architectural approach in many ways enhances the standard useful investigative questions of What, How, When and Why.

The idea is to create a LOGICAL view of the problem elements and possible solution components without any preconceived notions of what the final solution is or of how it is to be implemented. When the investigation is complete, then the structure of information can be reconsidered for relevance and importance with the degree of impact assessed for all cause & effect relations. From the key information elements various alternative options can be drawn up for final consideration. The solution space should now contain a range of alternative options not constrained by the PHYSICAL determination of how they are to be implemented.

Having a set of architectural principles to follow will act as a guide in the search through the problem space for the critical information components useful in the construction of an

Figure 1. Unstructured vs. structured planning

architectural reference model. This will give a systematic approach to the problem investigation and of the solution development. It will also encourage a broader review of the problem area and of the solution space.

When a final choice is made for the components that will make up the solution then the plan for how the solution is to be implemented should be documented using the guidance of the architectural reference model based on the above structure and the architectural principles and thereby following the standard that all staff will understand.

Defining Architectural Principles

Principles are the fundamental laws or doctrines for something; they are not rules for which the action is more specific but are guidelines to the requisite action. Guimarães (2012) in developing ideas to guide the development of an enterprise architecture for use in the financial market puts forward the following definition “principles are high-level definitions of fundamental values that guide the IT decision-making process, serving as a base for the IT architecture, development policies, and standards”. This definition unnecessarily limits the definition to the IT aspect of the architecture however, the definition is well suited for any problem solving domain, leave out the term IT and the definition suits the more general case. Although his use of the term ‘principle’ is more to do with the way to run the business than determining the structure of the business.

Aier et al. (2011) follows the development of the concept of enterprise architectural (EA) principles which are used as a means to develop a transition model for the enterprise: to establish a ‘TO BE State’ or ‘strategic plan’ for the enterprise. The EA principles are developed from requirements for strategic developments for the organisation and is framed by rationale, key actions and measurements, this takes a slightly different focus from McKee (2013). In McKee (2013) the architectural principles are aimed at the development of the Reference Model first, for a problem

area or solution state, and uses the reference model to guide the description of the ‘AS IS’ state prior to the development of the ‘TO BE’ state of the enterprise. The other difference in McKee (2013) is that the term ‘enterprise architecture principle’ is replaced in the strategic plan with ‘strategic objective’, framed by rationale, critical success factors, key actions and measures; as can be seen there are similarities in the supporting description of each approach.

Aier (2014) follows on from the discussion in Aier (2010), to research the role organisational culture has on the efficacy of the EA principles and has gathered a table of definitions from several authors for the enterprise architecture principles, two of the definitions are particularly interesting. One from Richardson (1990) “Principles are an organisation’s basic philosophies that guide the development of the architecture ... Principles provide guidelines and rationales for the constant examination and re-evaluation of technology plans” (p.389) and another from Lindstrom (2006) “Architectural principles define the underlying general rules and guidelines for the use and deployment of all IT resources and assets across the enterprise..” (p.2).

It is strange that these definitions of principles are on one hand limited to the technology plans and on the other, limited to IT resources. Each definition is much more powerful if the word technology is left out of the former and the word IT is left out of the latter. However if we replace the words ‘technology and IT’ with the word ‘business’ we get a very effective definition for use with the concept of ‘business architecture’.

In the search for a set of principles to use in developing an information architecture, the two definitions for ‘Enterprise Architecture’ developed by The Open Group were examined as follows:

- That architecture is “a formal description of a system or a detailed plan of a system at component level to guide its implementation”.

- That architecture is “the structure of components, their interrelationships, and the principles and guidelines governing their design and evolution over time” (Introduction, p.3).

The following architectural principles were derived from these definitions by McKee:

1. A formal detailed plan to guide implementation.
2. The plan should contain the components, their description and structure.
3. The plan should define the interrelationships between components.
4. The plan includes guidelines covering evolution over time (The rationale for why major components are there – which allows the rationale to be checked against changing circumstances).

Two other principles were added from other literature sources:

5. The plan should comprise several levels of abstraction from conceptual at the top linked to increasing detail at the next level.
6. The plan should include investigating environmental factors that surround the objective. (McKee, 2013).

These principles were then followed in the review of the business management and planning literature in order to develop an architectural reference model for use in creating the information architecture for presenting strategic planning information.

Developing an Architectural Model

A Reference Model (RM) is a conceptual framework to identify the major elements that comprise a concept and to show at a general level how these

elements are related with each other. As mentioned in the previous section the identified architectural principles are used drive the development of the reference model for the enterprise architecture. “A model is a representation of an important aspect of the real world. Sometimes the term abstraction is used because we abstract (separate out) an aspect of particular importance to us” (Satzinger et al., 2004, p.45).

Bearing in mind the above set of principles, the problem domain is surveyed for the elements that are most critical and the nature of important dependencies noted and the RM built accordingly. Once the RM has been discussed and validated then the RM can be used to construct the actual model of the business organisation from the business analyses (the Porter’s 5 forces and value system, the SWOT etc.) and then the cause and effect relations can be confirmed and the degree of association calculated/estimated.

The purpose behind modelling is to help design something, in this case the business architecture, to ensure that the real business operation and its market setting is correctly identified and represented. The process of creating the model helps the planner clarify and refine the design, the model acting as a communication tool and assisting the dialogue (Satzinger et al., 2004).

As an example of how the architectural principles can be used to aid the problem solving process the principles were used to create a reference information architecture as a template for managing the development of the strategic implementation plan. The concept flow of this idea can be seen in the Figure 2.

The requirements for developing a solution for the format of a strategic plan were determined from the business management and planning literature, firstly what the solution components could be, then determine what interrelationships between components should be defined. The following material for the reference model is drawn from McKee, 2013.

Figure 2. Concept flow to develop solution

1. Components suggested by the literature were:
 - a. Objectives,
 - b. Critical success factors (CSF) of the objective,
 - c. Actions needed to achieve objective,
 - d. Key performance indicator/s (KPI's) for achieving the CSF or action.
2. Relations were determined to be:
 - a. Direct linkage between related components,
 - b. Rationale for major components,
 - c. Degree of contribution to higher level component.
3. The next step was to determine what the reasonable levels of abstraction for the solution structure should be.

Level one was determined to be the focus areas of the organisation requiring attention and the objectives and CSF's needed to achieve success, level two shown in Figure 3 was the CSF's and action items needed for each objective and level3 was the detail of key performance indicators required for each CSF.

Figure 3 clearly shows the relationships between components and includes the rationales - why the objective is there and how the CSF contributes to the objective. The action item has the detail of due date for completion and who is responsible.

The principles provided a guide for the development of a reference architecture for the strategic planning problem and could realistically provide

Figure 3. Second level abstraction showing objective to CSF relationship

guidance for the development of a reference business architecture when examining the business management literature and the various papers on the business analysis tools such as Porters Five forces and Porters Value chain and value system etc. In a different problem space, market research or other analysis may provide additional information components that would be appropriate for the solution space.

Once the reference architecture is built it gives the planning team a communication template to fill in as required as the solution develops. The levels of abstraction and the direct linkages between information elements allows the problem to be worked on by different sections of the staff as appropriate and also allows the solution to be developed iteratively with prior areas revisited as more detail develops. This same method of working will allow the solution to be revisited on a regular basis during implementation and changes made as required due to changing circumstances.

A useful starting point for the development of a business focused architecture for an organisation might be to dissect the key aspects of an organisation's core logic of business processes (perhaps via Porter's value chain / value system) together with an analysis of the functioning of the business model (see above section headed 'Problems') and how that relates to the operation of the business. The overall business architecture might perhaps also contain a finance architecture, logistic architecture, supply chain architecture; whichever area of activity are of particular concern to that organisation

The complexity of all the information concerning the organisation leads to the idea to separate the business model, the organizational plan and the strategic plan into different documents; each with its own approach. This also separates the more dynamic information that needs to be reviewed regularly, from that information that is more static over time. With the organisational analysis structured into the organisational description (business architecture); the future planning can be iterative between developing the business

model and testing the strategic choices against the business model then selecting the optimal items for the strategic plan.

Each document should have a clear purpose and function as follows:

- The Business Architecture lays out the information of the AS-IS state from the organisational analyses.
- The Strategic choice document lays out the various options for improvement.
- The Business Model sets out how the organisation is to do business; including selecting the target customer segment and deciding on the value to that segment. By parsing the strategic choices against the business model, decisions can be made and choices selected for implementation - creating the strategic plan.
- The Strategic Plan is the summation of what developments the company is to pursue with the actions determined and the budgets and key measurements set in order to create the TO-BE state of the organisation.

It is important that with the problem divided into different documents (see Figure 4), that the interdependencies are clearly identified and the linkages shown between the related elements, as seen in Figure 3 above and in particular between the different documents.

FUTURE RESEARCH DIRECTIONS

It is essential for there to be reference architectures developed as examples and templates for more definable aspects of the business enterprise – the value chain would be a good example where the example reference model would demonstrate how to show the parts that are driven by the information system and those that are manual and indicating the relative value add for each aspect. These can then be used as discussion vehicles and would al-

Figure 4. Level 1 basic business architecture reference model

Source: Adapted from Alter, 2002; McKee, 2015

low them to be further developed and refined for use by businesses that wish to create a sustainable progressive environment for their organisation.

The set of components, relations and levels used above for an information architecture for the strategic plan could be used and developed in future research. Other researchers could add to this set or refine them when checking their suitability across different organisations or industries. Similarly the range of components and the sorts of interactions that could be expected could be developed for the business architecture.

The identified set of architectural principles could be tested and refined across a range of scenarios for developing architectures.

A white paper entitled “Platform Engineering Maturity Model” discusses the evaluation of the maturity level of an organisation’s computing software platform, the importance I feel is the idea that as the organisation uses more products that have *certification* then the more mature it is

(Momentum, 2011). The computing hardware and now the application software products and blueprints, recipes & services can be deemed to be *certified* when meeting standard operating procedure requirements. It is necessary to research and develop *certification* for reference architectures, frameworks and models for different organisational structures i.e. mining, manufacturing, retail etc.

As part of these reference architectures it would be necessary to refine the principles and define frameworks and models and describe their attributes and possible artifacts that can result from their use.

CONCLUSION

This paper has shown how the idea of architectural principles can be used to guide the development of an architectural reference model which can be

used to develop and present the organizational analysis in the model of the organisation. McKee (2013) demonstrates a set of reference models for information architecture in the relatively easy area (in terms of architecture) of strategic planning. Figure 4 shows a possible starting point for a business architecture reference model. The next step must be to refine a set of reference models for business architecture, and perhaps separate models for the supply chain, marketing finances, logistics etc., it would depend on the focus of the organisation. The various different industry segments, mining, manufacturing, retail sales etc., each would require their own approach to what constituted a useful reference model.

It would be a good step forward if there was an academic subject on business architecture in the MBA that would give the subject a more standardized view for a global audience rather than the multiplicity of short courses and competing different views being run at present.

Architecture by providing a blueprint of the whole enterprise with descending levels of abstraction and navigating links to the component parts and their interactions can be a powerful communication tool for the organisation. The possible advantages of architecture for improved decision making, improved adaptability to change, eliminating waste and optimization of resources make it a goal worth having. A larger goal is going beyond business architecture to the concept of developing an architecture for each different problem space, creating a template for solution development.

Finally a concluding statement from Reynolds that gives a good argument for spending the effort in creating an architecture for your organisation.

Where there is a business architecture, it becomes easy to build a portfolio of projects or initiatives that will help the business move forward in a strategic way, with each initiative bringing the business closer to the envisioned end state of the roadmap (Reynolds, 2009, p8).

KEY TERMS AND DEFINITIONS

Blueprint: A plan of action or a guide to doing something.

Framework: Aggregate of fundamental parts of a structure, or of those which hold the rest together.

Level of Abstraction: The different views of a system from high level to low level, where the high level can be decomposed into lower levels.

Model: A standard pattern or example to follow.

Principle: Ultimate source or origin of anything from which all else is derived. A general and comprehensive law, doctrine or truth as the basis for other laws.

Reference Model or Reference Architecture: Model to guide and improve. These models are sets of structured concepts, guidelines and/or solutions used to guide organisations through a process.

Service Oriented Architecture (SOA): A particular architecture where the application services are provided online through a service provider.

Benchmarking Performance Indicators of Indian Rail Freight by DEA Approach

B**Neeraj Bhanot***Dr. B. R. Ambedkar National Institute of Technology Jalandhar, India***Harwinder Singh***Guru Nanak Dev Engineering College, India*

INTRODUCTION

To accomplish the organization's logistics/distribution activities, measurement systems have been designed to capture information regarding five types of performance. These five categories are: asset management, cost, customer service, productivity and logistics quality (Li, 2005).

Li (2005) discussed several evaluation methods for logistics performance. Qualitative and quantitative data can be dealt by AHP method but the weight of different factors is objective. The result is influenced by the subjectivity greatly. Mathematic statistics method mainly conducts the quantitative data, and the evaluation process is objective. However strong qualitative analysis ability has been shown by Fuzzy comprehensive evaluation and Rough sets method. The above methods are not systematized as a whole. The objects, contents and methods are too much complicated to be integrated. But DEA (Data Envelopment Analysis) especially suitable for multi-input and multi-output complicated systems take the weights of input and output of DMU (Decision Making Units) for variables, evaluates in terms of DMU. In a word, DEA is more suitable evaluation method for the logistics activities as it has very strong objectivity.

Data Envelopment Analysis (DEA)

DEA measurement can be defined as the ratio of total weighted output to total weighted input. It is a linear programming-based technique that

converts multiple input and output measures into a single comprehensive measure of productivity efficiency (Epstein, & Henderson, 1989). DEA provides a measure by which one firm or department can compare its performance, in relative terms, with other homogeneous firms or departments. In measuring the relative efficiencies of organizations with DEA each organization can utilize different weights for the set of performance measures. Weights are selected that will maximize the composite efficiency score for each functional unit. Taking into account differences in goals, responsibilities, and type of procurement, this variable weighting allows for the evaluation of performance. The range of possible weights is controlled by requiring all weights to be positive, and specifying that if another unit used the same weight, their total efficiency score could not exceed the value of one. The technique also gives information as to the specific effect each input or output has on overall efficiency as yet, which has demonstrated its use as a potential evaluation tool for logistics performance. In summation, DEA can be used to reduce some of the existing problems with performance evaluation system (Charnes, Cooper, & Rhodes, 1978).

An examination of the literature reveals the application of DEA for performance benchmarking in a variety of settings such as telecommunications (Lupi, Manenti, Scialà, & Varin, 2011), educational institutes (Portela, Camanho, & Borges, 2011), productive efficiency (Farrell, 1957; Chandraprakaikul, & Suebpongsakorn, 2012; Holden, Xu, Greening, Piecyk, & Dadhich,

DOI: 10.4018/978-1-5225-2255-3.ch051

2016), Irrigation sector (Phadnis, & Kulshrestha, 2012), safety performance (Berih, Patnaik, & Mahapatra, 2011), etc.

Indian Railway Container Scenario

By taking over network of seven Inland Container Depots (ICDs) of Indian Railways (IR) located at Delhi, Ludhiana, Bangalore, Coimbatore, Guwahati, Guntur and Anaparti, Container Corporation of India (CONCOR) was incorporated in March 1988 as a Public Sector Enterprise under the Ministry of Railways. The company was formed with objective to have a separate organization for promoting and managing the growth of containerization in India as well as developing multimodal (surface, rail, water and air) transport logistics and infrastructure to support India's growing inland as well as international trade. Under the supervision of Managing Director, the day-to-day affairs of the business of CONCOR are managed by various divisional heads (CARE, 2009). Although, IR is a public sector monopoly, there is a growing demand on it to realize the full scope of its assets through proper use of systems and technology and also to address the lack of its customer orientation. Therefore, there is a strong need to devise a performance benchmarking system of its supply chain operations (George, & Rangaraj, 2008). To introduce competition in the container operations segment, the Ministry of Railways allowed the entry of private and public sector operators to obtain licenses for running container trains on the Indian Railways (IR) network in January 2006. Until then, the Container Corporation of India, a subsidiary of IR, was the monopoly operator of container trains in India.

This book chapter is an extension of previous study conducted on evaluating the performance of CONCOR over a period of time using super-efficiency analysis by employing CCR and BCC models of DEA considering different parameters for additional years to outline the key issues for needful improvement by validating the results of CCR and BCC models. The subsequent sections narrate thorough study of background of

performance evaluation perspective of logistics operations within and outside country. Further, DEA models, which are used in this study and the application of these models for benchmarking of Indian Railway Container Business within CONCOR, have been explained. The last section presents appropriate discussion on the results obtained and conclusions of the study.

BACKGROUND

Freight Container Business continued to be monopoly in the hands of government owned Container Corporation of India. In this section, history of performance evaluation has been discussed within and outside country in competitive scenario over the years in order to cite the various cases of performance oriented studies related to logistics.

Background Within Country

Napa (2006) discussed strategic moves and logistic operations, CONCOR took to establish it and face the challenges posed by the entry of new players. The task ahead in the company had been discussed in addition to questions, which can be taken as possible new problems for work. This framework further provides scope for readers to analyse various strengths and weaknesses of the CONCOR in the light of the future competition.

George, & Rangaraj (2008) analysed the performance benchmarking study of the zones of Indian Railways (IR) to develop an alternate approach for measurement of aggregate operational performance. The efficiency trends within the set of inputs and outputs considered with efficiency scores ranging between 58.26% to 100% by CCR and 58.26% to 254.92% by RCCR analysis identified the best performing railway zones over the years. The conclusion showed some weaknesses of the conventional DEA due to cross-efficiencies along with self-efficiencies and operating ratios.

Gangwar, & Raghuram (2010) examined the current policy environment from the point of view of business viability for 15 new Container Train

Operators discussing the various problems and prospects of Container Train Operators in India. It further brought out issues related to licensing, pricing, terminals, maintenance, and service levels found good response to the policy as entrants obtained licenses to run container trains. However, due to lack of clarity or inconsistency in matters pertaining to haulage charges, maintenance of wagons, transit guarantees from Indian Railways (IR) and terminal access charges, operators started feeling susceptible about the viability of the business.

Ghosh, & Bandyopadhyay (2014) investigated the efficiency of operating no-frill airlines (LCCs) in eastern India by collecting publicly available data of various parameters related to the technical and financial health of these airlines. Technical efficiency of each no-frill airline in comparison with other no-frill airlines was studied by employing Data Envelopment Analysis on the input and output variables. Further, Super Efficiency Model was applied on the most efficient airlines. The study thus helped in understanding the technical efficiency and performance of operating no-frill airlines in eastern India.

Performance Evaluation Study of Logistics Operations Within and Outside Country

Hilmola (2007) used DEA methodology to discuss about the efficiency and productivity of railway freight transportation sector in Europe. The analysis revealed that former Eastern Bloc and West European countries were showing the highest efficiency levels in the 1980s and experienced an efficiency collapse in the 1990s. Study on partial productivity analysis proposed that productivity of locomotives and railway tracks being primary target for productivity improvement in the highly efficient countries showed approximately 80% increase in transit traffic via rail in all the Baltic states.

Kunadhamraks, & Hanaoka (2008) evaluated the logistics performance of intermodal freight transportation using Fuzzy set theory to deal

with attitudes and perceptions within the decision process. Fuzzy-MCA was used to assess logistics operators' perception of the performance via proper assignment of numerical scores. Sensitivity analyses of significant variables were performed to examine the impact on changed costs and services levels and found that it can entail use of improved corresponding parameters to develop an efficient logistics system in Thailand.

Koster, Balk, & Nus (2009) used data envelopment analysis (DEA) on primary data of large container terminals, APMT (39 terminals) and European terminals of PSA (seven terminals) to discuss the reasons behind diverging results. Qingdao-APMT, Raysut/Salah-APMT, and Singapore-PSA-Brani were reported as the top three efficient terminals with 100% efficiency under CRS and VRS are all in Asia. Houston-APMT would be number four with 38% efficiency. The results differed strongly from those available in the literature and the reason for different terminal types and scales are mixed with the ports.

Mäkitalo, & Hilmola (2010) adopted methodology to foresee the future development of deregulated industries especially in the transportation sector. On the basis of a qualitative expert profiling analysis using Delphi questionnaire directed at 52 Finnish experts, as three different argument types existed in Finnish railway transport policy. Descriptions for each group based on material collected by the Delphi technique and concluded that the policy definitions have followed the views of the moderate group and the realization of the deregulation process has been slow. The research was limited to the Finnish railway freight transport market.

Hilmola (2011) developed efficiency benchmarking measurement models for public transportation systems to decrease environmental emissions in the future (CO₂), worldwide decreasing reserves of oil, and growing population in larger cities in line with the global agreements. The author used four different DEA based efficiency benchmarking models to evaluate public transportation efficiency in larger cities and found that medium sized, old and Central European cities

show frontier performance in all four models whereas Mega-cities fail to reach frontier and/or good performance.

Lee, Yeo, & Thai (2014) applied a slacks-based data envelopment analysis (SBM-DEA) model to assess the environmental efficiency of port cities by considering labor population in respective port cities as input variable, and gross regional domestic product (GRDP) and container throughput as output variables. The study also considered various undesirable output variables such as, nitrogen oxide (NO_x), sulfur oxide (SO₂), and carbon dioxide (CO₂) emissions. The results of the study indicated Singapore, Busan, Rotterdam, Kaohsiung, Antwerp, and New York as the most environmentally efficient port cities with Tianjin as the least environmentally efficient.

Shao, & Sun (2016) categorised the production process of air routes into two stages viz., allocation and transport, and then proposed two network data envelopment analysis (DEA) models to analyse the efficiency of the system, allocation, passenger transport, and freight transport of 477 air routes. The results of the study highlighted the significant impact of different constraints on intermediate measure in the network DEA models affecting the air routes' efficiency significantly. In addition to this, most of the air routes depicted high allocation and passenger transport efficiency with low freight transport efficiency.

MAIN FOCUS

Data Envelopment Analysis Approach

Linear programming (LP) multi-factor productivity analysis model Data Envelopment Analysis approach (DEA) can be used to measure relative efficiency of homogenous set of DMUs. It calculates a maximal performance measure for each DMU relative to all other DMUs with an objective that each DMU lie on or below the external frontier. Without requiring any specific assumptions about the functional form, it optimizes on each

individual observations with the purpose of calculating a discrete piecewise frontier determined by the set of Pareto-efficient DMUs. Each DMU not on the frontier is scaled down against a convex combination of the DMUs on the frontier facet closest to it.

The usual measure of efficiency, i.e.:

$$efficiency = \frac{output}{input}$$

is often inadequate related to different resources, activities and environmental factors due to the existence of multiple inputs and outputs. DEA methodology is developed to solve this problem.

There are two basic DEA models—CCR model, developed by Charnes, Cooper and Rhodes in 1978 and BCC model, developed by Banker, Charnes, and Cooper in 1984. CCR model generalizes the single output/input ratio measure of efficiency for a single DMU in terms of fractional linear programming (FLP) formulation transforming the multiple output/input characteristics of each DMU to that of a single “virtual” output and “virtual” input. The model defines the relative efficiency for any DMU as a weighted sum of outputs divided by a weighted sum of inputs where all efficiency scores are restricted to lay between zero and one. An efficiency score less than one means that a linear combination of other units from the sample could produce the same vector of outputs using a smaller vector of inputs. The score reflects the radial distance from the estimated production frontier to the DMU under consideration. In order to calculate efficiency scores, FLP is converted into LP by normalizing either the numerator or the denominator of the fractional programming objective function. In case of input-minimization DEA program, the weighted sum of outputs is constrained to be unity to minimize weighted sum of inputs while in output – maximization DEA program, the weighted sum of inputs is constrained to be unity to maximize weighted sum of outputs. CCR model is based on constant returns to scale assumption. Under this assumption, if the input

levels of a feasible input-output correspondence are scaled up or down, then another feasible input-output correspondence is obtained in which the output levels are scaled by the same factor as the input levels (Charnes *et al.*, 1978).

CCR Model

This model generalizes the usual input/output ratio measure of efficiency for a given firm in terms of a fractional linear program formulation. Mathematically, the relative efficiency of the k^{th} DMU is given by:

$$\text{Max } h_k = \frac{\sum_{r=1}^s u_{rk} y_{rk}}{\sum_{i=1}^m v_{ik} x_{ik}} \quad (1)$$

Subjected to:

$$\frac{\sum_{r=1}^s u_{rk} y_{rj}}{\sum_{i=1}^m v_{ik} x_{ij}} \leq 1 \quad \forall j = 1 \dots k \dots n$$

$$\frac{u_{rk}}{\sum_{i=1}^m u_{ik} x_{ik}} \geq \varepsilon \quad \forall r = 1 \dots s$$

$$\frac{v_{ik}}{\sum_{i=1}^m v_{ik} x_{ik}} \geq \varepsilon \quad \forall i = 1 \dots m$$

where: y_{rk} = the amount of the r^{th} output produced by the k^{th} DMU; x_{ik} = the amount of the i^{th} input used by the k^{th} DMU; u_{rk} = the weight given to the r^{th} output of the k^{th} DMU; v_{ik} = the weight given to the i^{th} input of the k^{th} DMU; n = no. of DMUs; s = no. of outputs; m = no. of inputs; and ε = a non-Archimedean (infinitesimal) constant.

The above objective function is reformulated in LP problem as follows:

$$\text{Max } w_k = \sum_{r=1}^s \mu_{rk} y_{rk} \quad (2)$$

$$\sum_{i=1}^m v_{ik} x_{ik} = 1$$

$$\text{Subjected to } \sum_{r=1}^s \mu_{rk} y_{rj} - \sum_{i=1}^m v_{ik} x_{ij} \leq 0$$

$$\forall j = 1 \dots n$$

$$\mu_{rk} \geq \varepsilon \quad \forall r = 1 \dots s$$

$$v_{ik} \geq \varepsilon \quad \forall i = 1 \dots m$$

Since the number of DMUs is generally larger than the total number of inputs and outputs, solving the dual of the model can reduce the computational burden. Mathematically, the dual formulation of the above model is:

$$\text{Min } z_k = \theta_k - \varepsilon \sum_{r=1}^s S_{rk}^+ - \varepsilon \sum_{i=1}^m S_{ik}^- \quad (3)$$

Subjected to

$$\sum_{j=1}^n \lambda_{jk} y_{rj} - S_{rk}^+ = y_{rk} \quad \forall r = 1 \dots s$$

$$\sum_{j=1}^n \lambda_{jk} x_{ij} + S_{ik}^- = \theta_k x_{ik} \quad \forall i = 1 \dots m$$

$$\lambda_{jk} \geq 0 \quad \forall j = 1 \dots n$$

θ_k free

$$S_{rk}^+, S_{rk}^- \geq 0; \quad r = 1 \dots s, i = 1 \dots m$$

where: S_{rk}^+ = Slacks in the i^{th} input of the k^{th} DMU; S_{ik}^- = slacks in the r^{th} output of the k^{th} DMU; λ_{jk} 's = non-negative dual variables; θ_k (scalar) is the (proportional) reduction applied to all inputs of DMU k to impose efficiency. If for DMU k , $\theta_k^* = 1$ and all slacks are zero, it is Pareto efficient. The non-zero slacks and (or) $\theta_k^* \leq 1$ identify the sources and amount of any inefficiency that may exist in the DMU under reference.

Efficiency scores are constructed by measuring how far a utility is from the frontier. A test DMU is considered inefficient if a composite DMU (defined as linear combination of units in the set) can be identified which utilizes less input than the test DMU while maintaining the same or greater output levels (Phadnis, & Kulshrestha, 2012).

BCC Model

The convexity constraint is the primary difference between BCC model and CCR model. In the BCC model λ_{jk} are restricted to summing to one (i.e. $\sum_{j=1}^n \lambda_{jk} = 1$). The model is converted into Non-Increasing Returns to Scale (NIRS) model, if we impose $\sum_{j=1}^n \lambda_{jk} \leq 1$ instead of $\sum_{j=1}^n \lambda_{jk} = 1$. Similarly if we impose $\sum_{j=1}^n \lambda_{jk} \geq 1$ instead of $\sum_{j=1}^n \lambda_{jk} = 1$, then the model is known as Non-Decreasing Returns to Scale (NDRS) model.

DEA Super-Efficiency Model

The discriminatory power of super-efficiency model provides insights that cannot be gained with the standard DEA model. The DEA score for the inefficient unit is considered as its rank scale. In order to rank scale the efficient units they allow the efficient units to receive an efficiency score greater than 100 percent by dropping the constraint that bounds the score of the evaluated unit. In standard DEA, Decision Making Units (DMUs) are identified as fully efficient and assigned an efficiency score of unity if they lie on the efficient frontier. Inefficient DMUs are assigned scores of less than unity (Yawe, 2010).

A number of uses have been proposed for super-efficiency models (Lovell, & Rouse, 2003). These include:

1. Ranking of efficient DMUs;
2. Classification of DMUs into extreme-efficient and non-extreme efficient groups;
3. Sensitivity of efficiency classifications;
4. Two-person ratio efficiency games;
5. Identifying outliers in the data;
6. Overcoming truncation problems in second-stage regressions intended to explain variation in efficiency;
7. Calculating and decomposing a Malmquist productivity index.

Super-efficiency measures are constructed by avoiding that the evaluated firm can help span the technology (Bogetoft, & Otto, 2011). Let $T^*(\gamma | -k)$ be a DEA approximation of the technology using the γ assumptions and based on all observations but that of firm k (Box 1).

Now the efficiency of (x^k, y^k) relative to $T^*(\gamma | -k)$ is called super-efficiency.

$$E^{SUPk} = E((x^k, y^k); T^*(\gamma | -k)),$$

$$F^{SUPk} = F((x^k, y^k); T^*(\gamma | -k)).$$

APPLICATION TO BENCHMARKING OF INDIAN RAILWAY CONTAINER BUSINESS

The above-described DEA models are used for the performance benchmarking of the Indian Railway container business. The implementation of DEA however involves recognizing the inputs

Box 1.

$$T^*(\gamma | -k) = \left\{ (x, y) \in \mathbb{R}_+^m \times \mathbb{R}_+^n \mid \exists \lambda \in \wedge^{K-1}(\gamma) : x \geq \sum_{j \neq k} \lambda^j x^j, y \leq \sum_{j \neq k} \lambda^j y^j \right\}$$

and outputs of the units being assessed, selecting measures for the inputs and outputs, collecting data on the inputs and outputs, solving the appropriate models and interpreting the results (Thanassoulis, Dyso, & Foster, 1987).

Inputs and Outputs/ Performance Indicators

The performance evaluation using DEA starts with selection of appropriate input and output measures that can be combined into a composite index of overall performance. Inputs are basically the different resources that the firms consume for its operations while the outputs represent a set of quantitative measures of results expected from these firms (George, & Rangaraj, 2008). In this study, they were chosen based on previous DEA studies reported in literature and also on the availability of data. Table 1 highlights the list of performance indicators used for the study.

Data Analysis

The secondary data from year 1994-95 till 2015-16 has been used for performance evaluation within CONCOR and shown in Table 2.

The secondary data from all the organizations has been collected through personal interviews. However Figure 1 shows methodology adapted in present study in a flow chart.

Table 1. Performance indicators to be used

S.No.	Performance Indicators	Type
1.	Number of Handling Terminals	Input
2.	Number of Employees	Input
3.	Number of freight wagons	Input
4.	Number of Containers (TEUs)	Input
5.	Net Profit (in Crores)	Output
6.	TEUs Handled	Output

Sources: Azevedo, Ferreira, Dias, & Palma, 2009; Morris, Pandey, Raghuram, & Gangwar, 2010; George, & Rangaraj, 2008; Hilmola, 2007

In order to gain deep insights in the study, Super-efficiency analysis have been deployed so as to verify the results by both CCR and BCC models. Further depending on whether inputs and outputs are controllable, a Decision Making Unit (DMU) can have either an input orientation or output orientation (George, & Rangaraj, 2008). As such the study is based on input orientation.

In order to evaluate the performance within CONCOR the years 1994-95 to 2015-16 have been the Decision Making Units (DMU's) along with respective inputs and outputs in order to determine the efficiency trends.

To reach the conclusion, Spearman Rank Correlation Coefficient (r_s) has been used to correlate the results shown by CCR and BCC Models as per the formulae below:

$$r_s = 1 - \left(\frac{6 \sum d^2}{n(n^2 - 1)} \right)$$

wherein, r_s varies from -1 to +1 and is weak positive correlated if its value is between 0 and 0.5 & strong positive correlated if its value is between 0.5 and 1. Same is the case with negative correlation when its value varies between 0 and -1.

RESULTS AND DISCUSSION

In this section, results for the performance evaluation within CONCOR from 1994-95 till 2015-16 have been suitably presented to highlight various constraints in order to improve their efficiency.

In case of analysis by Super-efficiency Model, Table 3 showed Efficiency Analysis for CONCOR by CCR and BCC models for the years 1994-95 to 2015-16 with fluctuation of 75.83% to 109.51% and 93.52% to 1000% respectively. The revelation through efficiency analysis using CCR and BCC models indicated a Spearman Rank Correlation Coefficient (r_s) value of 0.60, which clearly reflects a strong positive correlation value.

Table 2. Secondary Data for CONCOR from 1994-95 till 2015-16

Year	No. of Handling Terminals	No. of Employees	No. of Freight Wagons	No of Containers (TEUs)	Net Profit (in Crores)	TEUs Handled
1994-95	11	488	3835	7800	23.89	402632

2014-15	73	1331	13111	20247	1047.55	3110756
2015-16	73	1332	13471	20944	786.93	2924046

The years pertaining to lower efficiencies can be attributed to the lack of infrastructural facility and their proper management as visible from potential improvements as in case of CCR Model. While, in case of BCC Model, the lowest efficiency has been attributed to the year 1997-98 since the cargo handlings and exports were declined on account of incessant rains and floods causing disruption of traffic movement. Thus there was insignificant growth into logistic business. However, the successive years showed little better towards growth considering the efficiency improvement factor may be due to use of better managerial skills. The overall issues pertaining to lower performance have been presented at the end of analysis.

Table 4 and Table 5 again express the potential improvement by Super-efficiency DEA study for performance indicators by CCR and BCC models respectively, which indicates by how much, and in what areas an inefficient unit needs to improve in order to be efficient. The negative percentage shows the amount of reduction needed for highlighting the specific variables in order to increase the efficiency.

The CCR model analysis from Table 4 concluded that throughout the discussed inefficient years, it was evident that the number of employees and number of containers have shown highest requirement for potential improvement with percentage fluctuation varying between -44.87%

Figure 1. Methodology for benchmarking CONCOR performance by DEA approach

Table 3. Super-Efficiency Analysis within CONCOR

Year	Efficiency (CCR model)	Ranking (CCR Model)	Efficiency (BCC Model)	Ranking (BCC Model)
1994-95	83.24	5	127.27	21
1995-96	96.51	14	104.56	17
1996-97	103.19	19	103.53	16
1997-98	82.81	4	93.52	1
1998-99	84	7	94.89	2
1999-00	83.64	6	96.06	4
2000-01	78.93	2	99.14	8
2001-02	75.83	1	96.91	6
2002-03	81.72	3	98.7	7
2003-04	91.68	10	108.15	19
2004-05	87.75	8	102.49	15
2005-06	90.77	9	99.47	10
2006-07	95.77	13	101.29	12
2007-08	109.51	22	112.11	20
2008-09	104.73	20	105.07	18
2009-10	93.2	11	96.28	5
2010-11	101.98	18	102.25	14
2011-12	99.51	17	99.78	11
2012-13	99.84	16	101.48	13
2013-14	99.32	15	99.34	9
2014-15	109.23	21	1000	22
2015-16	94	12	95.27	3

to +9.51% and -47.98% to +6.81% respectively in comparison to other performance indicators.

However The BCC model analysis from Table 5 concluded that throughout the discussed inefficient years, the number of handling terminals have shown highest requirement for potential improvement with percentage fluctuation varying between -16.62% to +27.27% with requirement from number of freight wagons also with percentage fluctuation ranging between -11.77% to +12.11% respectively.

This percentage fluctuation in CCR and BCC models signifies the variation of percentage potential improvement and suitable reduction or enhancement in highlighted performance indicators could have increased the overall performance of

CONCOR for respective inefficient years. Thus the study from Super-efficiency DEA revealed some of the following issues which needs to be taken care of to improve and maintain the performance level of CONCOR:

- Focus of management remained developing the particular field instead of moving step by step in a planned strategy for all-round growth of the complete set of activities.
- It is also clear that no planned policy for infrastructure development was enforced whereas the licensing norms too added in-different scenario.

Table 4. Potential improvements performance indicator wise within CONCOR by CCR model through Super-efficiency analysis (in percent)

Year	No. of Handling Terminals	No. of Employees	No. of Freight Wagons	No of Containers (TEUs)	Net Profit (in Crores)	TEUs Handled

- The declines in the efficiency lead on account of unplanned expansion of terminals and infrastructure growth haphazardly without caring competitive strategies.
- The deficient services were due to monopoly of CONCOR till 2005, the work culture generally relied on irregular practices like pick and choose, bribery, tip to staff.

The strategic weaknesses and unplanned development can however be tackled efficiently as CONCOR has sufficient infrastructure in light of competition but there is a need to utilize it optimally and as of now, it seems that to some extent, proper measures have started being taken

to enhance the performance of the organization with reference to concurrent efficiency measures. However, it cannot be denied that the reliability of data is a primary concern which if forged will not lead to highlight the true issues, which reduce the efficiency.

CONCLUSION

The Super-Efficiency DEA study identified efficiency fluctuation between 75.83% to 109.51% (CCR Model) and 93.52% to 1000% (BCC Model) owing to lack of efficient staff and operational planning in rake management in addition to

haphazard infrastructure growth viz. number of handling terminals, number of handling equipments and containers without caring for optimal requirements and managing properly. The same being concurrent to licensing policy norms, which needs to be thoroughly formulated in a phased and realistic manner to boost up the trade and industry within the set of inputs and outputs considered. It will also be beneficial if CONCOR focuses on enhancing the productivity of staff by providing them suitable reading to enhance their skill level which ultimately will lead to enhanced performance level.

LIMITATIONS

Though a lot of advantages, there are limitations for this work as the private operators engaged in the transportation business of containers could not be directly approached owing to time and cost constraints. Only government operator being CONCOR has been considered for the internal performance evaluation over the period of time. Further the reliability of data provided by the operator for needful research is based merely on the information and available sources.

FUTURE RESEARCH DIRECTIONS

The present study can be extended to other private operators e.g. Adani Logistics, Reliance Infrastructure, etc. operating in other parts of India for their individual and competitive performance comparisons. It can also be expanded by considering some more performance indicators viz. Cost, Service/quality, Productivity, etc. to gain deeper insights to enhance the performance of the organizations.

KEY TERMS AND DEFINITIONS

Benchmarking: It is a management tool through which a plan for evaluation, measurement, and improvement is implemented.

Container Corporation of India: Container Corporation of India Ltd. (CONCOR) is a Category I Miniratna Public sector undertaking under the Indian Ministry of Railways. Incorporated in March 1988 under the Companies Act, Concor commenced operations in November 1989 taking over an existing network of seven inland container depots (ICDs) from Indian Railways.

Data Envelopment Analysis: Data envelopment analysis (DEA) is a nonparametric method in operations research and economics for the estimation of production frontiers. It is used to empirically measure productive efficiency of decision making units (or DMUs).

Indian Railways: Indian Railways (IR) is an Indian state-owned enterprise, owned and operated by the government of India through the Ministry of Railways.

Performance Evaluation: The analysis in terms of initial objectives and estimates, and usually made on site, of accomplishments using an automatic data-processing system, to provide information on operating experience and to identify corrective actions required, if any.

Super-Efficiency: The Super-efficiency analysis allows calculating efficiency improvements for efficient units.

Bi-Directional Business/IT Alignment

INTRODUCTION

Business/IT alignment – as the process of aligning business and IT to achieve organizational objective and competitive advantages – is a core task of information management (IM) with implications for IT innovations management. Recent research has revealed the need to depict business/IT alignment as bi-directional process in IT governance frameworks to appropriately capture customer-driven IT requirements (Bartens et al., 2016; 2014a; 2014b; Chen, 2008; Patel, 2002, 2004).

The requirement for a bi-directional business/IT alignment becomes obvious regarding the case of e-business (Bartens et al., 2014b) and in two-sided markets (Bartens et al., 2016, 2014a). In this context, technological development often leads to altered customer requirements that trigger a need to adjust business models. Prominent examples can be observed in the media streaming movement. For a long time media were sold as products such as books, records, DVDs, etc. With the emergence of streaming technology, the respective business models faced a drastic need to adapt to flexibility and technology requirements of customers. While those requirements are incorporated in the discussion around buzz words like digital transformation (Patel & McCarthy, 2000) and digital transition (McFadden, 2012), they involve the reversal of the causal chain of requirements in IM. In contrast to current approaches, as the top-down business/IT alignment in the IT governance framework COBIT 5, in these business models, requirements can emerge out of the business operations and

may be defined by the customer. The business cooperation of T-Mobile and Spotify Inc., where the fulfillment of customer needs required the adjustment of both business models (Bartens et al., 2016), may serve as a specific example.

Current IT governance frameworks, definitions and models of IM predominantly still assume a one-directional top-down business/IT alignment process (Krcmar, 2010; Singh & Woo, 2009; Voß & Gutenschwager, 2001; Wollnik, 1988). Thus, they neglect the requirements of changing business models, e.g., in e-business. In the light of the work by Pérez Lorences and García Ávila (2013) as well as De Haes et al. (2013), IM and IT governance is a focus of discussion here and it is put into perspective in this article. Pathways on how IM models and definitions should be extended to integrate bi-directional business/IT alignment are introduced. The remainder of this article is structured as follows. Section 2 provides a brief literature review of IM and business/IT alignment. Section 3 proposes possible extensions of current IM models and definitions to cover bi-directional business/IT alignment. Section 4 gives conclusions and implications for related research.

BACKGROUND: FUNDAMENTALS OF BUSINESS IT/ ALIGNMENT

In this section, a background on the fundamentals of business/IT alignment is given. The alignment of the strategic plans of a business and its IT can be considered an important responsibility and

DOI: 10.4018/978-1-5225-2255-3.ch052

function of IM (Krcmar, 2010). Furthermore, the current state of IM and business/IT alignment is defined and presented in the following.

Information Management

While a broad range of definitions on IM — even contradicting ones — are proposed in literature, the definition by Voß and Gutenschwager (2001) serves as a fundament for the discussion in this article. According to Voß and Gutenschwager, IM is seen as the economic (efficient) planning, acquisition, processing, distribution and allocation of information as a resource for the preparation and support of decisions (decision-making), as well as designing the required infrastructure for this purpose. Applying a similar definition, the majority of authors, argue that IM can be subdivided into several fields of action. One of them is a strategic field in which business IT/alignment as well as the definition and implementation of IT governance are key functions (Boaden & Lockett, 1991; Choo, 2002; Sabherwal et al., 2001; Krcmar, 2010; Voß & Gutenschwager, 2001). The above definitions do not explicitly incorporate business/IT alignment, but the distribution of information in order to support decisions and designing the corresponding circumstances as, e.g., described by Voß and Gutenschwager (2001), may be understood as an abstract depiction of a business/IT alignment process.

Business/IT Alignment and IT Governance

The idea of aligning business and IT functions in order to facilitate business value through the usage of IT has received plenty of attention in recent years (Chan & Reich, 2007; De Haes et al., 2013; Luftman & Kempaiah, 2007; Van Grembergen & De Haes, 2009). Important contributions were provided by the studies of Henderson and Venkatraman (1993; 1999) and have been taken as reference by many authors up to today. In this line, Duffy (2002) describes business/IT alignment

as “the process and goal of achieving competitive advantage through developing and sustaining a symbiotic relationship between business and IT.” Recognizing the previously presented explanations on the definition of IM, business/IT alignment is widely considered part of IM (Maes et al., 2000).

Currently, scientific and practical insights on business/IT alignment are dominated by top-down approaches (Chen, 2008; J. C. Henderson & Venkatraman, 1993; Kearns & Sabherwal, 2007; Kooper, Maes, & Lindgreen, 2011; Lainhart, 2001; N. V. Patel, 2002, 2004). In practice, business/IT alignment is often guided by IT governance frameworks. The COBIT 5 Goals Cascade (ISACA, 2012a), e.g., applies a top-down alignment in this context (ISACA, 2012b; Krcmar, 2010; Van Grembergen & De Haes, 2009). Nonetheless, recent research reveals the existence and need of bottom-up alignment processes (Bartens et al., 2014b). In its origin this need is identified in highly dynamic environments, as well as sectors where the influence of IT on operations is above average. The acknowledgement and combination of the given single aspects by different authors form a holistic array of arguments for a transferability of this hypothesis to a general viewpoint. At this point, the contributions of Györy et al. (2012) (user-driven innovations, shadow IT), Patel (2002) (emergent organizations), Bartens et al. (2014a, 2014b, 2016) (merger of IT management and operations, requirements in two-sided markets) as well as Chen (2008) (bottom-up requirements and alignment) have to be mentioned.

BI-DIRECTIONAL ALIGNMENT IN INFORMATION MANAGEMENT

The introductory sections revealed the ties between business/IT alignment and IM. In the following, the integration of the recent approaches on considering customer-driven or bottom up-requirements in business/IT alignment is outlined and IT governance implications are discussed. In addition, the proposed model is contrasted against different

Figure 1. Integrated bi-directional information management model

definitions on IM and the views on this topic in frameworks such as COBIT 5 and ITIL 2011.

A Bi-Directional Information Management Model

As a general framework, IM research often refers to structured layer models (Galliers & Leidner, 2014; Maes et al., 2000). Such an approach was proposed by Wollnik (1988) and adapted in various later publications (Galliers & Leidner, 2014; Krcmar, 2010; Maes et al., 2000; Voß & Gutenschwager, 2001). Nevertheless, these models neither explicitly incorporate bi-directional alignment structures. Figure 1 now incorporates the bi-directional/IT alignment paradigm by extending the original layer model of information management by Wollnik. The three layers interact via a requisitioning and supportive relationship with each other. Requirements are defined as top-down, while support relations are bottom-up (Krcmar, 2010; Voß and Gutenschwager, 2001). In order to integrate the bi-directional business/IT alignment, valuing this task as a key element within the realm of IM, the requirements relationships to a bi-directional interface are extended. In addition, the inputs on information demands and the preceding demand analysis are now extended over all three layers as well.

The proposed modification enables organizations to identify processes and implement customer-driven (Bartens et al., 2014b), especially more generic, bottom-up issued requirements (Chen, 2008). In addition, the model's extension is applicable to other fields and (communication, interaction, and coordination) processes of IM as well as in between IM — particularly applying to the IM tasks definitions formulated by several authors (Galliers & Leidner, 2014; Krcmar, 2010; Voß & Gutenschwager, 2001). In this sense, an altered IM definition, extending the definition by Voß and Gutenschwager (2001), may assume IM as the economic (efficient) planning, acquisition, processing, distribution, and allocation of information as a resource to support and design decision-making, as well as designing the required infrastructure for this purpose. This extended definition now explicitly allows IM to design decision-making, i.e., to align a business model according to bottom-up requirements. Bearing in mind the introductory example of media business, the proposed IM model now provides orientation in the challenges these business models face. It generates fundamental awareness for technological evolution that may require re-designing the business model. In the media streaming case, the model illustrates that, by implementing streaming technology (as an innovation), revenues can no

longer be generated from selling physical goods and may be replaced by subscriptions. Obviously, this model just provides strategic orientation; specific implementations are guided by IT governance (frameworks).

Two Directions of Alignment in IT Governance

While business/IT alignment is discussed in IM research, it is also addressed from the angle of IT governance (De Haes & Van Grembergen, 2015; Van Grembergen & De Haes, 2009). In this realm, the aspects related to IT governance and the frameworks COBIT 5 and ITIL 2011 are examined. As shown by Bartens et al. (2014b) COBIT 5 (ISACA, 2012a) does not reflect a bi-directional business/IT alignment. The main criticism is found due to the strict top-down structure of the key alignment instrument, the COBIT 5 Goals Cascade. Bartens et al. (2014b) postulate that in e-business a merger of the business and IT side of an enterprise as well as the customer side (through the business operations) occurs. Within these merged structures bottom-up requirements evolve on a regular basis. In order to stay competitive, enterprises classified as e-business models, have to accommodate these requirements in a structured and dynamic way as well as in a timely manner. The transition of the authors' findings to businesses outside of the e-business sector can be assumed due to the number of initiatives (hybrid business models) or even the high rate of transformation from pure brick-and-mortar businesses to e-business models (Patel, 2004).

Despite the general focus on the customer, it can be argued that a bi-directional paradigm within ITIL 2011 (Cannon, 2011; Steinberg et al., 2011) is only limited. Main arguments are found in the overall control of change proposals by the service provider (Cannon, 2011) and top-down design coordination (Cannon, 2011) as well as the improvement processes (Lloyd et al., 2011). On the other hand, a complete neglect of bi-directional actions is not observed. Especially

the recently added processes of "strategy management" and "business relationship management" consider customer feedback in a bottom-up approach, though its management is still structured top-down (Cannon, 2011).

Most importantly, note that the aspect of a merger of business and IT operations together with the customer are purposely counteracted by the restrictive structure (Krcmar, 2010) of ITIL processes. No hints on possible mergers can be found within the operations publications (Steinberg et al., 2011), even though merged structures naturally occur where IT influence and dependency is high (Bartens et al., 2014b). Here, the need for a constructive approach as self-claimed by ITIL is potentially the highest overall. A solitary exception is given by workarounds, as seen in "problem management" (Steinberg et al., 2011), which are independently created and implemented by operations. Still, this only refers to temporary solutions, neither a permanent process for requirements satisfaction nor IT innovations management. Depending on the interpretation and depth of application of the proposed model and the underlying bi-directional approach, one may still argue that the basic concepts are at least recognized at a high level.

FUTURE RESEARCH DIRECTIONS

With the bi-directional model of IM the theoretical fundamentals of bi-directional business/IT alignment are given, and future research directions may examine implications for various aspects in IM and IT governance. While IT governance may be concerned with more practical issues of the bi-directional paradigm, IM research may also rethink the role of IT for the competitive position of an enterprise and come up with altered models for IT innovation management. Related research in IT governance will need to provide solutions for bi-directional alignment with the frameworks COBIT and ITIL. Future research may, furthermore, discover required extensions

in IT innovations management models. Also, bi-directional business/IT alignment may be described for different IM models.

CONCLUSION

Recent research has highlighted the need to model customer driven bottom-up business/it alignment in IT governance. This led to the question whether this new understanding of business/IT alignment is reflected in definitions and models of IM. In this article, it has been examined to which extent this new aspect is covered in IM and described possibilities for an integration or extension of IM models. It was found that IM models generally allow a bi-directional business/IT alignment, but hardly specify it in a way that reflects customer needs for technological changes. Consequently, an extension of an established layer model of IM has been provided. Subsequently, a novel specification in IM was introduced and implications for IT innovations management were demonstrated as well as IT consulting approaches were highlighted. In addition, pathways to handle the implications of our findings were elucidated.

KEY TERMS AND DEFINITIONS

Bi-Directional Business IT Alignment:

The process and goal of achieving competitive advantage through developing and sustaining a symbiotic relationship between business and IT, while emphasizing an often omitted bi-directional alignment between business and IT.

Business /IT Alignment: The process and goal of achieving competitive advantage through developing and sustaining a symbiotic relationship between business and IT.

COBIT: An IT governance framework and toolset that allows managers to bridge the gap between control requirements, technical issues and business risks (ISACA).

Information Management: The economic (efficient) planning, acquisition, processing, distribution and allocation of information as a resource for the preparation and support of deci-

sions (decision-making), as well as designing the required infrastructure for this purpose.

IT Governance: Framework function for the administration, organization, and control of IT in enterprises and public organizations.

ITIL: Framework that aligns IT services to the needs of the business and support its core processes.

Layer Model of Information Management: A structuring model that defines layers of information management, e.g., with respect to the level of technology used.

Business Sustainability Indices

B

Arunasalam Sambhanthan
Curtin University, Australia

INTRODUCTION

Sustainability indices are integral part of measuring the process level variables in an organism (i.e. county, region, city, industry, organization, business unit). The documented literature has less evidence for targeted indices developed for measuring specific industry clusters / organizational units. In fact, there are indices which are developed by researchers to measure the sustainability in a country or regional level (Böhringer & Jochem, 2007). These indices are meant to assess the sustainability at policy level applicable for countries and organizations in general. However, there is a considerable research gap in terms of indices which are developed for measuring the ICT Business Sustainability. This paper aims at reviewing the existing sustainability indices in the body of literature.

BACKGROUND

Business Sustainability research has been tremendously progressed. However, it is still a question as to how well the concept of business sustainability has been theorized. Theorizing business sustainability has a number of challenges to be tackled in terms of which aspects are critical for sustainability and which are not. Therefore, it is essential to have a theoretical model as the basis for theorizing business sustainability elements. This paper reviews the two types of theoretical models available in the business sustainability research namely the sustainability hierarchy and business sustainability typology. The relevance of the concept of sustainability to business domain is paramount.

DOI: 10.4018/978-1-5225-2255-3.ch053

THE SUSTAINABILITY HIERARCHY

Four sustainability frameworks have been identified as ‘ambiguous with regard to what is being sustained’. The label ‘unsustainable’ has been categorized into four levels of actions which prevent sustainability of any kind. This led towards the development of a Sustainability hierarchy (Marshall & Toffel, 2005) which was constructed using several distinct but related concepts (refer to Figure 1).

The above hierarchy is an action centered hierarchy which looks at the sustainability from a hierarchical model as depicted above. The model is based on the hierarchy of needs theory propounded by Abraham Maslow. The needs theory indicates that the satisfaction of lower level needs leads towards the higher level need in the hierarchy. The same metaphor is applied here for environmental sustainability in this context. The achievement of a lower level environmental metric leads to the achievement of the higher level one in the hierarchy.

The main shortcoming of this model in terms of applying to business sustainability is its lack of specialization to business domain. The model is named as sustainability hierarchy which could be applied to anything which has the ability to be applied to the sustainability research. Therefore, the above model is argued to be not contextually relevant for assessing and benchmarking sustainability in organizations. A definition of business sustainability goes as “adapting business strategies and activities that meet the needs of the enterprise and its stakeholders today while protecting, sustaining and enhancing the human and natural resources that will be needed in the future” (International Institute of Business

Figure 1. Business sustainability hierarchy

Sustainability). Therefore, the following section focuses on reviewing the business sustainability typologies out there in the literature.

THE SYSTEM BASED SUSTAINABILITY BUSINESS MODELS

Models to assess business sustainability have been less documented in the literature. Besides industry specific frameworks there are a number of common frameworks out there in the literature such as the European Corporate Sustainability Framework (ECSF) (Costanza & Patten, 1995), there have been less documented models out there in the published literature to assess and benchmark business sustainability. The industry specific frameworks and the ECSF all could be classified as frameworks than of models. The System Based

Sustainability Business Model documented by (Dyllick & Muff, 2013) has four characteristics such as economic characteristics, environmental characteristics, social characteristics and multidimensional or social characteristics – each of which is attributed into two attributes namely structural attributes and cultural attributes.

There are a number of structural attributes that have been found within the economic characteristics. For example, bodies external to the organisation that keep track of performance of the companies that uses a triple bottom line approach and the government that keep track of changes to taxation system and legislation to support sustainability and local shareholders and investment in local sustainability initiatives. The environmental characteristics consists of structural attributes such as a threefold strategy which offsets (do no harm but make amends if you do), sustainable (do no harm), restorative (leave the world better than you

found it), closed-loop systems which is responsible for product throughout its lifecycle implementing a services model and the industrial ecosystems and stakeholder networks. The social characteristics includes attributes such as stakeholder engagement skills - understanding stakeholders' needs and expectations (i.e. being relevant to stakeholders), educating stakeholders - "relentless" communication implementing stakeholder consultation program and getting "buy-in" from internal and external stakeholders. The multidimensional characteristics has been structurally attributed with cooperative business strategy and planning, collaborative model including supply chain, competitors, government agencies, communities, TBL approach to measure organizational performance, institutionalize sustainability in the business: "relentless" communication, stakeholder education, leadership, champions, and align internal performance measures and demand-driven model, not supply-driven model (driven by what people need, not driven by companies trying to get people to buy more).

The cultural attributes associated with economic characteristics includes attributes such as profit is a means not an end. Business makes a profit to do something more. "Higher purpose" to business than making money, shareholders invests for social & environmental impact reasons as well as for financial reasons and shareholders temper expectations for short term financial returns. The environmental characteristics have only one cultural attribute which looks at treating nature as a stakeholder. The social characteristics attributed for culture are stakeholder approach (managing the organization for the benefit of all stakeholders and not prioritizing shareholders' expectations above other stakeholders), alignment of stakeholder expectations, sharing of resources (people, profits, and time) among stakeholders to achieve sustainable outcomes and the relationship building (trust, two-way loyalty, honesty, integrity, and fairness, equity). Finally the multidimensional characteristics have been attributed for culture

with a number of attributes such as medium to long-term focus and reduction in consumption.

This business model is quite comprehensive to evaluate business sustainability, but essentially lacks to incorporate the fourth bottom line - institution into it. In fact, the fourth dimension has been identified to be playing a critical role in determining the sustainability of organisations at the current milieu with WEDC proposing it as an additional bottom line for sustainability evaluation. In addition to this, the social dimension of the above model is identified to be overly emphasising on stakeholder engagement, but lacks to incorporate the human resources issues in social sustainability of organisations - a critical aspect. For an example, the employability and other human resource issues arising in organisations could be included into this dimension to make the social sustainability dimension more relevant to the business sustainability research agenda.

BUSINESS SUSTAINABILITY TYPOLOGY

There is not much documented research in terms of defining the typologies of business sustainability. An early research by (Costanza & Patten, 1995) pose few questions regarding defining and predicting sustainability. The paper deals with the sustainability of systems. The critics questions about the usefulness of the concept of sustainability due to the ambiguities involved in properly defining the term. Hence, the discussions of this regard are argued to be misdirected due to the following reasons:

1. The discussions were arguing the problem as definitional instead of predictive which deals with the prediction of what will last and survive in achieving the consensus on what we want to last
2. The discussions failed to account for the range of interrelated time and space scales over which the concept must apply

Hence, the authors argues that the basic idea of sustainability is very simple and straightforward as a sustainable systems is one which services or persists over the time. However, there are three main concerns to be addressed in this regard. Firstly, it should be clarified as to what system or subsystems or characteristics of the system persist? For how long it is going to persists? And when it is going to be assessed as to whether it has persisted? In overall, the paper is trying to address the above questions.

- **When?:** Although the paper discusses about the biological point of view of sustainability, it is avoided in this discussion due to the fact that this discussion is targeted on the business aspect of sustainability. In economic point of view, sustainability is all about avoiding major disruptions and collapses, hedging against instabilities and discontinuities. In this context, it could be argued that the sustainability of businesses could not be defined in present tense, as it is very hard to predict as to how long a business will last. In fact, the sustainability of a business could only be termed after the period of existence it has. Therefore, it is quite contradictory to argue whether sustainability is a concept which needs to be defined in present tense or past tense. Whereas, predicting sustainability is technically possible, the authors argues that defining sustainability is impossible due to the time and space constraints involved in defining the concept of sustainability. The actions taken today in order to prevent the system will contribute towards the sustainability in the future. Whilst, making an effort to define a future stage could be considered as more of an attempt to predict, it could also be argued whether it is feasible to predict something solely based on the present stage of the particular system or organism. Thus, the authors argue that a possible definition of sustainability could

be a set of predictions of actions taken today that will lead to sustainability in long run. This entails the consideration of system uncertainties as a bottleneck in defining business sustainability.

- **What?:** What system or subsystem one has to sustain in long run is the second question? This dimension indicates the preferred characteristics as an element of sustainability. Thus the three sub elements of the characteristics highlighted by the authors include scale of economy, distribution of resources and allocation of resources. The above characteristics are argued to be the predictors of the sustainability of a system or sub-system.
- **How Long?:** This involves with the time span of the sustainability of system concerned. Some arguments foster the everlastingness as systems' sustainability. However, infinity cannot be a timespan to be specified for sustainability. Therefore, it is a vital concern to consider the time length when speaking about the sustainability of any system.

In contrast, a research documented by (Dyllick & Muff, 2013) looks at three compartments such as concerns, organizational perspective and value created. The business sustainability typology outlined by (Dyllick & Muff, 2013) is depicted in table 1.

The above typology shows three different versions all of which is described with the aforementioned three compartments (Muff & Dyllick, 2014). The first compartment covers concerns such as consuming the income than of capital and being accountable for the impact of business decisions and activities. The second component looks at concerns such as managing risks and opportunities, increasing market share, revenue and reputation. The third dimension looks at integration of economic, ecological and social value creation.

Table 1. Business sustainability typology

Typology of Business Sustainability	Concerns (What?)	Organizational Perspective (How?)	Values Created (What for?)
Business-as-usual	Economic concerns	Inside-out	Shareholder Value
Business sustainability 1.0	Three-dimensional concerns	Inside-out	Refined shareholder value
Business Sustainability 2.0	Three-dimensional concerns	Inside-out	Triple bottom line
Business Sustainability 3.0	Starting with sustainability challenges	Outside-in	Creating value for the common good

In addition to this, the authors are outlining three versions of business sustainability which has been presented as the business sustainability typology theorization basis by (Muff & Dyllick, 2014). The basis of versioning this has been justified based on the Input => Process => Output logic. In fact, the version 1 states business sustainability as an approach and the version 2 define it as a process while the version 3 claim it to be the impact / effect on the environment. Therefore the business sustainability typology outlined by (Dyllick & Muff, 2013) could be argued as the first step in business sustainability typology research with more opportunities for applied research in this domain with the typology proposed by (Muff & Dyllick, 2014).

SUSTAINABLE PRODUCTION

Sustainable production is an area of paramount concern by businesses which involves any form of production. In fact, (Veleva & Ellenbecker, 2000) argues there is no comprehensive framework for assessing business sustainability. Regardless of the above absence in the literature, there are a number of business sustainability frameworks, developed and documented by researchers in the recent literature which are constructed using a number of sustainability indicators (Høgevold & Svensson, 2012); (Pojasek, 2007); (Hardjono & De Klein, 2004). The indicators for sustainable production as outlined by (Veleva & Ellenbecker, 2000) includes energy and martial use (resources), natural environment, Economic viability, com-

munity development and social justice, employees and products. The above indicators aim to inform business decision makers and co-operate policy makers with the principles of sustainable production that will eventually lead towards compliance to global standards on production sustainability. In addition to this, (Quinn & Dalton, 2009) outlines a number of principles for enabling companies to have sustainable production which includes elements such as products and packaging, energy and materials, workplace practices, economic viability and community development. However, it is questionable whether the indicators covered by the aforementioned authors cover a whole range of industries which involves production of various goods and services. For example, some of the industries which uses technological resources for production such as software and e-learning would need to have indicators for sustainable production which will include e-waste and code reuse. On the contrary, there could be a number of practical issues related to the intellectual property and non-disclosure agreements between client-business partnership that could prevent the code reuse and related sustainability measures at instances. The following section evaluates the qualities of sustainable production indicators in detail.

INDICATORS FOR SUSTAINABLE PRODUCTION

Integrating the sustainability concept into the production process is another core challenge in meeting the sustainability standards. This entails

the companies to reduce the resource intensity used in production process which would eventually lead towards sustainable production. Whilst evaluating the ways and means of integrating sustainability thinking to the production process, this section reviews the existing literature with the aim of outlining the desirable qualities of the indicators for sustainable production. Table 2 depicts the major qualities of the indicators of sustainable production as outlined by (Veleva & Ellenbecker, 2000).

The above qualities are of importance in valuing the indicators of sustainable production to an extent. Whilst the above indicators emerged from the early research on sustainability, there was a vacuum for concrete indicators for the measurement of sustainability reported by researchers (Veleva & Ellenbecker, 2000); (Böhringer & Jochem, 2007). On the other hand, it is questionable whether the aforementioned qualities are matching with the indicators denominating the sustainability of technology based industries (i.e. software, e-learning). In fact, most of the qualities outlined in the above table are of common for all

industries. In contrast, (Veleva & Ellenbecker, 2000) build an argument that it is a reality to have a standard set of indicators applicable to any company. The authors justify their argument stating that it is advantageous to measure the right things approximately than measuring the wrong ones with great accuracy and precision. For example, sustainability could be achieved through effective process redesign and production waste management (i.e. peripheral waste) in the context of software industry, whereas some other aspects of sustainability might get relatively low priority. Moreover, the companies could have innovative approaches for resource utilization in order to achieve sustainability in a product or service based technology led company. Whereas, indicators are considered to be in the second stage of an abstraction process (data -> Indicators / indices -> Frameworks - > Definitions), frameworks are considered to be the more concrete form of a sustainability theory next to definitions. Thus, the following section will examine the business sustainability frameworks available in the existing body of knowledge.

Table 2. Qualities of sustainable production indicators after

Indicator	Description
Appropriateness	The indicator's appropriateness to the task. This focuses on precisely and specifically expressing the unit of measure in the task.
Standardization	This looks at the ability to have a standard criteria using which a possible comparison could be made between two companies.
Data Availability and Accuracy	This enables the businesses to start with a single indicator of existing easily collectable data.
Verifiability	The credibility of reported information could be diluted if the data processed is not objective enough to make conclusions.
Set of Indicators	Set of indicators will allow the businesses to have a comprehensive coverage of sustainable production.
Inform Decision Making	Enabling the management regarding the concerns and priorities of the employees.
Manageable Number	The number of indicators employed needs to be manageable in order to eliminate the errors occurs due to the manageability.
Simplicity and Meaningfulness	The indicator needs to be simple as well as meaningful in terms of information richness.
Measurability	The indicators need to be quantifiable in terms of qualitative as well as quantitative aspects.
Consistency	Consistency between national sustainable production initiatives and sustainable production initiatives.
Community Involvement	Employees, community and interested stakeholder involvement is important for sustainability initiatives.

Veleva & Ellenbecker, 2000

A REVIEW OF SUSTAINABILITY MEASUREMENT INDICES

Whilst making the production and consumption of goods make a paramount contribution to the business sustainability literature, it is commonplace that the measurement indices for business sustainability are a lacking area in the existing literature. There have been a number of indices developed by researchers to facilitate the measurement of sustainability in differing contexts (see Table 3). For example, there are eleven sustainability indices documented by (Böhringer & Jochem, 2007) which looks at measuring sustainability at country level.

Whilst aiming to measure the sustainability of countries in different terms, the aforementioned eleven indices make meaningful contribution to the sustainability literature. For instance, the Living planet index has a direct contribution to the measurement of sustainability of species living across this planet. Another example would be the Environmental Performance Index that aims at measuring the environmental stresses which could affect the human health condition and sustainability. However, one of the main weaknesses of all these indices relies on its scope and measurement object. In fact, these indices are all focused on measuring the human ecosystem and the natural environment of a country, which does not have any direct contextual relevance to the measurement of business sustainability. On the contrary, a number of measurement criteria set forth for measuring the sustainability of a country could be applied for modelling the same phenomenon in an organization. For example, The Environmental Performance Index (EPI) has an element of measuring human health condition of a country as measurement criteria to assess the environmental sustainability. This could effectively be applied to an organization as well, since one of the measurement criteria for measuring business sustainability is health and safety of the employees and workers. Another drawback identified among these indices is the

lack of a cross-country comparability of indices. For instance, the Well-Being Index calculated for one country could not be compared with the Well-Being Index of another country. Hence, all these indices are useful in measuring the sustainability at country level, but not necessarily be suitable to measure business sustainability. Therefore, the following section focuses on a review of business sustainability indices out there in the literature.

MEASURING BUSINESS SUSTAINABILITY

Measuring business sustainability has been a long question in front of researchers. Measuring the triple bottom lines in terms of sustainability is paramount for any organization to survive. There are indices created by researchers at policy level which could facilitate the measurement of a country's sustainability as reviewed in the previous section. In contrast, there should be certain measurement scales for benchmarking sustainability at business level. One example would be the Dow Johns Sustainability Group Index which covers a range of sustainability indices. The index was created by S&P Dow John Indices which consists of a number of regional indices such as DJSGI World Index, DGSGI Europe Index, DGSGI North America Index, DGSGI Asia Pacific Index, and DJSGI USA Index. The index is recorded to be covering more than 2000 largest capitalized companies, 64 industries and 34 countries with over 231 components. This index is also documented for having a number of specialized indexes such as DJSGI excluding Alcohol indexes, DJSGI excluding Gambling indexes, DJSGI excluding Tobacco indexes, DJSGI excluding all indexes (i.e. excluding alcohol, gambling and tobacco). This index covers a number of issues such as Illegal commercial practices e.g. tax fraud, money laundering, antitrust, balance sheet fraud, and corruption cases, workforce conflicts e.g. extensive layoffs and strikes, large disasters or accidents e.g. fatalities, accidents, workplace safety, technical

Table 3. Sustainability indices after

Index / Sub-Indices	Description
Living Planet Index (LPI)	“LPI measures trends in over 2000 populations of more than 1100 species of vertebrates in terrestrial, freshwater, and seawater ecosystems” (Böhringer & Jochem, 2007)
Ecological Footprint (EF)	“The ecological foot print is based on the quantitative land and water requirements to sustain a (national) living standard into infinity thereby assuming certain efficiency improvements” (Böhringer & Jochem, 2007)
City Development Index (CDI) 1. Infrastructure Index 2. Waste Index 3. Health Index 4. Education Index 5. City Product Index	1. “Infrastructure index builds on four (equally weighted) indicators as percentages of households which are connected to clean water, canalization, electricity and phone network (without mobiles)” (Böhringer & Jochem, 2007) 2. “A twofold (equally weighted) waste index, which is composed of the percentage of untreated sewage in total wastewater and the percentage of disposal of solid wastes” (Böhringer & Jochem, 2007) 3. “A twofold (diversely weighted) health index, which considers the life expectance and the infant mortality rate” (Böhringer & Jochem, 2007) 4. “A twofold (equally weighted) education index which is calculated by adding the percentages of literacy and combined enrolment” 5. “A city product index, which is based on the logarithmic value of a city’s GDP” (Böhringer & Jochem, 2007).
Human Development Index (HDI)	“The Human development Index consists of three (equal weighted) sub-indices which are aggregated by an arithmetic mean: Life Expectance Index, Education Index (decomposed into and Adult Literacy Index and a Gross Enrolment Ration Index), and a GNP Index” (Böhringer & Jochem, 2007).
Environmental Sustainability Index (ESI)	“The Environmental Sustainability Index score quantifies the likelihood that a country will be able to preserve valuable environmental resources effectively over the period of several decades” (Böhringer & Jochem, 2007).
Environmental Performance Index (EPI)	“The Environmental Performance Index addresses the need for a gauge of policy performance in reducing environmental stresses on human health and promoting ecosystem vitality and sound natural resource management” (Böhringer & Jochem, 2007).
Environmental Vulnerability Index (EVI)	“The Environmental Vulnerability Index Consists of 32 indicators of hazards, 8 indicators of resistance and 10 indicators that measure damage” (Böhringer & Jochem, 2007).
Index of Sustainable Economic Welfare / Genuine Progress Index (ISEW/GPI)	“The starting point of the Index of Sustainable Economic Welfare is the inflation-adjusted consumption of households. The time series consumption values is adjusted by five categories to obtain a ‘GDP’ which is more appropriate for measuring social welfare: (1) distribution of income, (2) economic activities not counted in the conventional gross national income, (3) time adjustments, (4) damage caused by economic activity, and (5) the consideration of net capital endowment of foreign investors” (Böhringer & Jochem, 2007).
Well-Being Index (WI)	“The Well-Being Index is the arithmetic mean of a human Well-being index (HWI) and an Ecosystem Well-Being Index (EWI). The indices HWI and EWI in turn consist of five sub-indices. The HWI comprises a health and population, welfare, knowledge, culture and society as well as for resource deployment. The five dimensions of the HWI are based on 36 indicators, those of EWI on 51 indicators” (Böhringer & Jochem, 2007).
Genuine Savings Index (GSI)	“The Genuine Savings (GS) are an indicator of weak SD. The societal capital stock consists of produced capital, human capital (knowledge, skills etc.) as well as natural capital (resources etc.)” (Böhringer & Jochem, 2007).
Environmental Adjusted Domestic Product (EDP)	“The Green Net National Product or likewise the Environmentally Adjusted Net Domestic Product (EDP) has been developed within the scope of SEEA (System of Integrated Environmental and Economic Accounting). There are three different versions of the EDP can be distinguished: (1) the EDPI which subtracts depreciations of natural resources caused by their extraction from the Net National Income (NNI), (2) the EDPII, which subtracts from the NNI the costs necessary to reach the same state of the environment at the end of the period as existed at the beginning of the period, and (3) the EDPIII, which subtracts the costs of environmental pressure and destruction (calculated by willingness-to-pay methods)” (Böhringer & Jochem, 2007).

Source: Böhringer & Jochem, 2007

Table 4. Focusing on the automobile industry

Bottom-line	Indicator	Metric / Method	Driver for Inclusion
Environmental & Health	Life Cycle Global Warming Potential	Greenhouse emissions along the life cycle (vehicle production, driving 15555 KM based on EUCAR agreement, end of life) - Part of an LCA according to ISO14040	Carbon intensity is the main strategic issue in the automotive industry
	Life Cycle Air Quality Potential	Summer smog creation potential (POCP) along the same life cycle (VOCs, NO _x) – part of an LCA according to ISO 14040	Non CO ₂ air quality issues have to be monitored for trade offs
	Sustainable Materials	Recycled & natural materials related to all polymers	Resource scarcity
	Restricted substances	Vehicle interior air quality / allergy-tested interior, management of substances along the supply chain (15 point rating)	Substance risk management is key
	Drive-by-exterior noise	Drive-by-exterior noise = dB (a)	Main societal concern
Social	Safety	Including number of all EuroNCAP stars (see note under acronyms regarding EuroNCAP ¹)	Main direct impact
	Mobility capability	Mobility capability (luggage compartment volume plus weighted number of seats) related to vehicle size	Crowded cities (future: diversity – disabled)
Economics	Life Cycle ownership costs	Vehicle price plus 3 year's fuel costs, maintenance costs, taxation minus residual value (note: for simplification reasons costs have been tracked for one selected market; life cycle costing approach using discounting)	Customer focus, competitiveness

failures, ecological disasters and product recall. It is a question whether all these elements are really necessary to measure business sustainability. In fact, many of the issues listed in the above two categories are overly focused on measuring the sustainability of countries and cities than businesses. Whilst listing the above categories as the key factors for evaluation, the DJS group index lacks to include the institutional dimension in its evaluation criterion, which could be noted as one of the main shortcomings of this index. In addition to this the DSJ sustainability index has a regional classification of indices, but lacks to have an industry based classification, although the industry based classifications are used as a way for assessing the results to an extent. However, this is not targeted for assessing business sustain-

ability and there are not so many indexes other than this to measure business sustainability in the documented literature.

PRODUCT SUSTAINABILITY

There is not much documented research with regard to Product Sustainability Indices except the Ford of Europe's Product Sustainability Index (Schmidt, Wulf-Peter & Taylor, 2006), which supports measuring a vehicles' product sustainability throughout the entire product lifecycle along all three bottom lines. Table 4 depicts the details of product sustainability index measurement criteria proposed by (Schmidt, Wulf-Peter & Taylor, 2006) for measuring the sustainability of vehicles.

FUTURE RESEARCH DIRECTIONS

A number of future research directions are highlighted for subsequent treatment.

1. An analysis of industry specific sustainability indices.
2. An analysis of sustainability indicators in practice for different industries.
3. An analysis of sustainable indices in practice for different industry segments.

CONCLUSION

Theorisation of business sustainability has been dealt in this article. We have reviewed two types of business sustainability models in this article namely action centred models and construct centred models. Action centred model reviewed include the sustainability hierarchy which uses an action centred hierarchy to model sustainability. Construct centred models include system based sustainability business model and the business sustainability typology. The review indicates that there is not much documented research exist in business sustainability typologies. There is a considerable amount of research effort required from the applied researchers working in this area to contextualise and re-specify the business sustainability typologies to differing industry clusters such as e-learning, agriculture, manufacturing and healthcare. Furthermore, this paper has reviewed the sustainability measurement indices out there in the published domain. Primarily a number of researches have been reported on the sustainable production and the sustainable production indicators. Appropriateness, standardization, data availability and accuracy, verifiability, indicators, inform decision making, manageable number, simplicity and meaningfulness, measurability, consistency and community involvement are the sustainable production indicators reported in the past research. In addition to this there are a number of sustainability measurement indices such as Living Planet Index, Ecological Footprint, City

Development Index, Human development Index, Environmental Sustainability Index, Environmental Performance Index, Environmental Vulnerability Index, Index of Sustainable Economic Welfare / Genuine Progress Index, Wellbeing Index, Genuine Savings Index, Environmental Adjusted Domestic Product. A number of shortcomings which are not addressed by these indices has been discussed in the article and followed by a discussion about the Dow Johns Sustainability Group Index - which is the only index available in the literature to measure business sustainability. This paper serves as an introductory review to the sustainability indices and the applicability of those indices to the context of businesses.

The Business Transformation Framework, Agile Project and Change Management

Antoine Trad

Institute of Business and Information Systems Transformation Management, Switzerland

Damir Kalpić

University of Zagreb, Croatia

INTRODUCTION

In order to restructure and make the global economy agile in a sustainable manner, the integration of business engineering related Agile Project and Change Management (for simplification in further text the term *Project-Management* will be used) mechanisms are fundamental. *Project-Management* transforms traditional business environments to become a part of the newly interconnected global economy (Trad & Kalpić, 2014b). An important factor in continuously transforming a business environment into an innovative and lean business engineering services-oriented environment are the roles of the Business Transformation Manager (for simplification in further text the term *Manager* will be used) and the needed business transformation framework that has *Project-Management* capabilities. These capabilities are also needed to support dynamic project management activities, in order to facilitate project management's integration, manage critical success factors selection and risk assessment management. *Project-Management* must be used to schedule, manage, assert, govern, automate, trace, monitor and control the Business Transformation Project (for simplification in further text the term *Project* will be used) artefacts (Trad & Kalpić, 2015a; Trad & Kalpić, 2015b; Trad, 2015b). The *Manager's* role is of crucial importance for the implementation phase of complex *Projects*; where his or her (for simplicity reasons the authors will use his/he in further text) project management decisions can be made

in a just-in-time manner using outputs from the business environment's existing events, monitoring, audits and logging systems. Unfortunately, an agile holistic approach for project management, change management and enterprise architecture is very complex to implement (Lee & Yong, 2010).

The *Manager* must have the needed *Project-Management* skills to handle the complex and chaotic technical implementation phase of *Projects* that are the major cause of very high failure rates (CapGemini, 2009). Therefore the implementations of business engineering resources in *Projects* require specific advanced *Project-Management* techniques and that are defined in the initial architecture strategy. A *Project-Management* curriculum must contain project management, combine management sciences, risk management, law assertion, enterprise architecture, team management, technology management and business engineering sections (Trad & Kalpić, 2016). Such a curriculum or a certificate of advanced studies program should contain project management, engineering, risk assessment and technology and enterprise architecture topics. For this specific goal the Institute of Business and Information Systems' Transformation Management (IBISTM) has developed: a) a real world framework; b) an education curriculum; c) a training syllabi; and d) a set of certification programmes, to support *Managers* and hence *Projects* (IBISTM, 2016a).

This research proposes the *Project-Management* component that is a part of the Project management (Pm) module and this module is in turn a

part of the Selection management, Architecture-modelling, Control-monitoring, Decision-making, Training management and Project management Framework (SmAmCmDmTmPmF, for simplification in further text the term *Environment* will be used), that supports various aspects of *Project's* activities. In this article the authors present a set of *Project-Management* various types of recommendations and a reusable architecture pattern (ISO, 2000; ISO, 2007; Trad 2015c; Trad 2015d). The *Environment's Project-Management* must be synchronized through the architecture development method's phases, as shown in Figure 1, where each *Project* implementation building block circulates through the Architecture Development Method's (ADM) phases. The building blocks contain sets of Critical Success Factors (CSF) (Sugumaran & Lavanya, 2014) that can be applied for: a) the selection of the *Managers*; b) the implementation of *Project's* architecture and modelling strategies (Trad, & Kalpić, 2014c); c) the decision support system, in order to estimate the actual status of the *Project* and to decide whether to stop or continue the on-going project (Gartner, 2013); d) the *Project-Management*; and e) the training and educational needs of the *Project's* team.

BACKGROUND

The global research topic's and final research question (hypothesis #1-1) is: "Which business transformation manager characteristics and which type of support should be assured in the implementation phase of a business transformation project?" The targeted business domain is any business environment that: a) uses e-communication and business engineering technologies; and b) has frequent transformation iterations. For this phase of research the sub-question (hypothesis #6-2, as it will be seen from the further text) is: "What is the impact of agile project and change management on enterprise architecture and business transformation projects?"

In this research phase the authors are targeting the *Project-Management* component's integration that is a part of the Project management module (Pm) and its influence on *Projects* (Trad, 2015d). Actually we are experiencing the start of automation of project management and its integration enterprise architecture environments, but this integration phase is still immature. This is a barrier for a successful *Project's* management and has to be handled. In this article the authors use credible sources, proof of concept, industrial experiences gained and lessons learned from surveying many enterprises; and the first step is to define the ADM's, *Project's* and *Project-Management's* unit(s) of work.

MAIN FOCUS OF THE ARTICLE

Enterprise Architecture's Role

Projects, *Project-Management* and enterprise architectures are well-defined practices for conducting enterprise transformations, enterprise analysis, design, planning, and implementation, using a holistic approach at all times, for respecting a successful strategy. The main goal is to structure complex Information Technology (IT) systems in terms of their business, application, information, and technical layers, and to revise programs through *Project-Management* planning processes, as illustrated in Figure 2. Such organizations have to apprehend various techniques and methodologies before integrating complex frameworks like The Open Group's Architecture Framework (TOGAF) in their organization, as shown in Figure 2.

The proposed *Project-Management* is founded on TOGAF's ADM and the needed synchronization interfaces, as shown in Figure 3. The synchronization interfaces represent an asset for the initiation, development and maintenance of a *Project*; optimally automatable in both senses.

Technology is getting complex to manage, due to various problems with project management is-

Figure 1. The Environment's interaction with the project and change management component

Source: Trad, 2015c; Trad, 2015d

sues, like security, infrastructure, methodologies, management concepts, software development, business architecture etc. Therefore, micro changes that have minor implications on the *Project*, have to be implemented and as shown in Figure 4, are easy to be governed. The *Project* team should manage the micro changes and integrate them in the ADM's phases H, G, and F.

The Architecture Development Phase

The ADM can be enforced with *Project-Management* that adds a spiral model making the *Project*

iterative, this approach adds quality insurance and helps to deliver solutions on time, as shown in Figure 5. After the initiation of the *Project*, the designed building blocks that pass through each ADM's phase are updated with the new change requests. Each ADM iteration automatically updates and notifies the *Project-Management*'s scheduling tools and the *Project* plans. That means that the *Project-Management* schedule is dynamically generated and that represents a major *Project* or business benefit.

In the *Project*'s implementation phase, the developers' role is crucial, where their skills

Figure 5. The spiral model

Source: UML, 2015

always represent two undeniable *Project* assets which can boost the *Project* towards success or failure. As shown in Figure 5, the Unified Modelling Language's (UML) spiral model can serve as a dynamic bridge between the *Project*, *Project-Management* and the ADM's phases, where their communication relies on standards like the Project Management extensible Mark-up Language format (PMXML).

The Maintenance

The *Project* has an evolutionary and not a revolutionary approach and it is recommended that the migration process and the interaction between the *Project-Management* and ADM make such a process possible. Because each ADM's iteration is reflected to the *Project-Management* and that makes migration planning and maintenance a playground where all *Project* teams come together and

propose different changes that are synchronized with a *Project-Management* scheduling tool (Moe, Dingsøyr, & Dybå, 2010). The evaluation of each new change can be tested prior to its migration by simulating it with a corresponding CSF.

PROJECT AND CHANGE MANAGERMENTS' ROLE

Skills

The *Environment* defines the skills that are required for the *Project-Management's* integration in the *Project*, in order to deliver. These skills selection criteria should match TOGAF's Roles Program in order to select *Manager*. As shown in Figure 6, *Project's* project management skills typically comprise: a) managing business changes; b) project management methodologies; and c) development tools. The *Manager* must have also strong negotiation and problem-solving skills to work with the Project Management Office (PMO) in order to take the right decisions in just in time manner to keep the *Project* on track (The Open Group, 2015d).

Project Management Office

The PMO assists in the execution of *Project* Life-cycle Processes, which are based on best practices from standardized methodologies like Prince2 and TOGAF (Guiry, 2015).

STRATEGIC VISION, PLANNING, AND GOAL(S)

Project-Management is complementary to the ADM and as a matter of fact, the *Project-Management* should map to the organizational structure to the deliverables for each department that is led by a *Manager*. The *Manager* must have the skills for development of *Projects*, however modern business environments adopt a matrix project approach where each team is managed by more than one *Manager*. This fact can result in *Project-Management* collisions that can cause major delays, because several *Projects* can create unnecessary repetitive and endless *Project* activities like meetings that are due to disagreement between the leaders and team members.

A Holistic Agile View

The *Manager* must achieve an agile holistic view on the *Project* and such an agility should be integrated in its ADM, as shown in Figure 4 (APMG international 2011; The Open Group 2015c). The *Project-Management*, audit, risk and control mechanisms compose the core of enterprise's governance (ITGI, 2007; Tan, Carter, & Toleman, 2009).

Business Engineering and the Role of Standards

This *Environment* is based on technology and business engineering standards (OASIS, 2006) to insure that business engineering services' architecture and their *Project's* interfaces comply with the system's holistic concept. Actual advanced technologies like Management extensible Mark-up Language (XML) based architecture insure interoperability between all the *Project's* components in order to simplify the interface of the *Project-Management* to other components.

BUSINESS TRANSFORMATION AGILITY

Business transformation agility can be achieved by combining various agility methodologies and by using a bottom-up approach. The *Manager* should achieve the optimal business transformation agility needed to cope with the *Project's* implementation complexities. Agility is today supported by various methodologies and concepts that can be adapted to the ADM by using:

1. Lean software development methods which focus on the enterprise's value stream and are build on an atomic services concept. Lean development glues the enterprise, information system, *Project-Management* resources, and user into the company's value stream. *Project-Management* agility achieves: a)

success throughput low latency; b) planning reactive to change; and c) the focus on process and people (Coplien & Bjørnvig, 2010).

2. A lean project management framework can be assisted with the Scrum framework. Scrum is used for complex *Projects* in which failure rates are high and their complexity is impossible to predict. Scrum is a framework that has related best practices to make *Project's* development feasible (Beedle, 2001), and it allows to do just in time changes to keep the *Project* on track (Schwaber, 2004).
3. The initiation phase of a *Project* starts with a starting project package which can contain: a) a feasibility study report to support a proof of concept; b) contract documents; c) project terms and conditions; and d) responsibilities of the *Project's* team members.
4. Change management techniques for managing continuous changes permit the *Manager* to apply a deterministic approach to project management in order to manage structured plans, Gantt charts and various types of dynamic planning schedules. A framework like Scrum enables to adapt to *Projects* that are prone to frequent changes without the need for huge changes in the *Project-Management's* roadmap (Schwaber, 2004).
5. The *Manager* is a ScrumMaster, who is responsible for coaching other team members to face the *Project's* complexity (Schwaber, 2004). The *Manager* is also an Architect of Adaptive Business Environments (AofABE) and assumes the role of a ScrumMaster that fills the position of a project manager by using a Scrum framework. Traditionally, the project manager is or was responsible for defining and managing the *Projects*, as shown in Figure 7 (Schwaber, 2004).
6. Because of very high failure rates in *Projects* that are due to various types of human conflicts; heroic project's management might appear necessary (Cordier, 2013).

Figure 7. Scrum skeleton

B

7. Standardized project management methodologies like Prince2 and Project Management Professional (PMP) can be adapted in order to adapt to the ADM's fast iterations, by the use of import and exports procedures.

gaps between the Baseline and Target Business Architectures. Business architecture, as shown in Figure 8, uses the following types of models: a) Business Process Models (BPM); b) Use-Case Models; and c) Class Models.

Business Architecture

Business Architecture (BA) describes how the enterprise needs to operate to achieve its business goals and to respond to its strategic drivers that are set in the Architecture Vision process. This process addresses the Request for Architecture Work format and manages the stakeholder concerns in order to identify the candidate architecture roadmap's components that are based on

AGILE DECISION SUPPORT

Critical Success Factors

The selected Critical Success Factors (CSF) enable the *Project-Management's* filtered data that are logged into the monitoring database to be used for evaluation and problem solving purposes. The *Project* is based on BPMs which use CSFs to enable the evaluation of historical data-patterns.

Figure 8. Shows basic business architecture information technology requirements

All the ADM's phases manage the same set of selected CSFs to support the evaluation of encountered *Project* status, problems, requests, capabilities and objectives. CSFs are incorporated into the *Environment* and are CSFs will be updated with each ADM phase iteration's outcomes. The *Project's* tasks are fed into the *Project-Management* that can eventually reschedule the *Project* plan. PMXML plays a major role in the automated communication between the *Project-Management* and the ADM.

Decision Support System

Project evaluation or decision making addresses two major types of decisions: a) tangible; and b) intangible. Tangible decisions are the decisions which can be quantified and are based on measurements; where the best solutions are achieved by *Project-Management* automation. The *Project-Management* automation will facilitate and reduce the duration of the ADM's life-cycle; whereas intangible decisions require human interaction. The *Environment's* applied *Project-Management* component feeds the *Environment's* decision

module, which is based on an empirical problem-solving algorithm uses CSFs. This decision module is specialized for *Project* problem solving and is based on a heuristics engine and has potential to improve the competitiveness of the business enterprise. The *Environment* presents a new approach for decision module, where this approach can be applied by the modification of an *Project* plan (Sreka & Slaninova, 2012).

The *Environment*'s decision module delivers a set of possible solutions that determine the *Manager*'s skills and assists the *Project* in solving various types of *Project-Management* problems, such as possible critical paths (Trad & Kalpić, 2014a). The case of complex *Projects*, project scheduling tools need to display information coming from the ADM in a cascade manner; in other words, one task would contain a group of sub-tasks; this facilitates the *Project*'s governance to manage unexpected problems (Ylimäki, 2006).

Types of Management Risks

Management of risk is central for managing the outcomes of any *Project* change effort and there are two levels of risks that should be considered (The Open Group, 2011a): a) the Initial Level of Risk; and b) the Residual Level of Risk. As shown in Figure 10 the ADM's phases, including phase M, phase H and phase G are important for governing the *Project*; this governing process includes monitoring of: a) various governance requests; b) new developments initiatives; and c) change requests, when a change is requested, the

Figure 10. Shows the various project phases

change management process will initiate a new architecture evolution initiative.

Initial Risk Assessment

The combination of frequency and effect can help in quantifying the *Project*'s risk assessment. In order to find the solutions for the preliminary risk assessment, the decision module must be used; however, there are no instant rules for quantifying the effect and frequency factors.

Conduct Residual Risk Assessments

Once mitigation efforts have been identified for each CSF risks, continuous re-evaluation of the effect and frequency have to be done; the final deliverable of this process is the transformation risk assessment that could be estimated.

Figure 11. Business capability management

Source: The Open Group, 2011a

Figure 12. The interaction between standardized frameworks

Control Objectives for Information and Related Technology Framework

The Control Objectives for Information and Related Technology (COBIT) is a business framework for the governance and management of business environment's information system and insures that globally accepted standards, practices and models support the quality of the *Project*. (TOGAF, 2013; Sutherland, Viktorov, Blount, & Puntikov).

Information Technology Infrastructure Library

The standardized Information Technology Infrastructure Library contains a well detailed description of a seven-step improvement process that provides the capabilities to: 1) measure; 2) plan; and 3) implement business services improvement and their needed assertions. This seven-step improvement process is not only used on an operational level but it also provides support for all the ADM's phases (Van Sante & Ermers, 2009). In this seven-step improvement process the *Project* team implements the needed service level agreements that can be incorporated in the *Project-Management*.

SOLUTIONS AND RECOMMENDATIONS

Proof of Concept

The Proof of Concept (PoC) or solution was built using: a) Microsoft's project management environment; b) the XML standard export; and c) Microsoft Visual Studio; to support the following requirements:

1. To use the research's *Environment* including all its components.
2. That the *Project's* team uses enterprise architecture tool(s) to model the *Project* iterations; where the ADM phases create a class diagram that is used to generate the *Project-Management's* project plan.
3. That the ADM's class diagram entities, use the "1:1" mapping concept to inherit task class properties, like: a) title; b) task-id; c) start-time; d) end-time; e) priority; etc... The inherited task class properties are entered in the project plan.
4. That the ADM class relationships are deduced to create the project plans dependencies and critical path(s).

5. That the ADM class test driven development components are used to find the statuses of the completion and they are injected into the *Project-Management's* project plan as the project plan status.

Recommendations

This research initiative is part of a long series of publications related to business engineering, enterprise architecture and business transformation projects; and is based on a mixed action research model; where the *Environment's* critical success factors and managerial recommendations are offered to help *Managers* and enterprise architects to decrease the chances of failure. For that goal a real world framework is offered with a set of architecture, technical and managerial recommendations. The most important recommendation that was generated by the previous research phases was that the business transformation manager must be an Architect of Adaptive Business Environments (Trad & Kalpić, 2014a). The used literature review sources and the *Environment's* PoC proved the feasibility of this research phase and delivered the recommendations on how to implement a *Project-Management* component. These recommendations are:

1. The *Manager* is an Architect of Adaptive Business Environments and he must be also a Scrum master.
2. The *Project* adopts a holistic systemic agile *Project-Management's* approach that is based on enterprise architecture's ADM.
3. The ADM can be enforced with *Project-Management* outputs that add a spiral model, to the make the *Project* iterative.
4. The ADM's initial phase defines the *Project-Management* roadmap.
5. In order to insure the optimal unit of work that will align all *Project* resources the use of a "1:1" mapping concept is needed (Trad, 2015a; Trad, 2015b). Apply a "1:1" mapping concept for all the *Project* artefacts that can comprise ArchiMate diagrams, UML diagrams, project plans, class diagrams...
6. A *Project-Management* curriculum must combine project management, management sciences, risk management, legal aspects, enterprise architecture, team management, technology management and business engineering (Trad & Kalpić, 2016).
7. In the *Project's* implementation phase, the developers' role is crucial where their skills represent an undeniable asset, to avoid very high failure rates in *Projects* that are also due to various types of human conflicts; that is why heroic *Project* management might appear necessary (Cordier, 2013).
8. The *Project* has an evolutionary and not a revolutionary approach and it is recommended to apply a migration process as an interaction between the *Project-Management* and the ADM to make such a transformation process possible.
9. Standardized project management methodologies like Prince2 and Project Management Professional standards can be adapted in order to adapt to the ADM's fast iterations, by the use of import and exports procedures.
10. The *Manager* must deploy a multivendor strategy and an anti-locked-in approach, where the *Project-Management* component must be designed to open to the ADM and project management standards. To achieve this strategic goal, Availability and Performance Monitoring and the use of interfaces for Unified Monitoring Solution for the control of *Projects*, must be implemented and linked to the *Project-Management* component (Kowall & Fletcher, 2013).
11. The decision making module uses the *Project's* logging system's database using the critical success factors that determine which *Project-Management* item must be checked and logged (Şeref, Ravindra, Ahuja, & Winston, 2007).

12. Integrating other standardized frameworks like the Information Technology Infrastructure.

FUTURE RESEARCH DIRECTIONS

The *Environment* future research will focus on a neural network based decision making module, which use a micro services concept.

CONCLUSION

In this research article, the focus is on how to integrate the *Project-Management's* component in a *Project*. The authors' aim is to offer an agile *Project* management concept; that can be used to view the vision and to define the best possible set of CSFs. The *Project-Management* communicates dynamically with the ADM and from a technological perspective this type of communication offers three major advantages for the *Project*: a) clear initiation; b) iterative development; and c) successful migration. The clear initiation presents a well-defined structure, with a governable set of the *Project* activities to be exported from the *Project-Management* to the ADM. The *Project's* iterative development enforced with frequent prototypes ensures the quality of the end system. For the *Project-Management*, migration planning goes to another level of abstraction where non-technical agents can intervene on all levels of the *Project*.

The *Environment's Project-Management* managerial, architectural and technical recommendations and a real-world *Environment*, round up the *Environment's Project-Management* component's characteristics for business transformation projects.

KEY TERMS AND DEFINITIONS

ADM: Architecture Development Method.

AofABE: Architect of Adaptive Business Environments.

Critical Success Factors: Can be used to manage the statuses and gaps in various project plans and gives the Projects the capacity to proactively

and automatically recognize erroneous building blocks and to just-in-time reschedule the Project plan(s).

Environment: It is this research's framework.

Manager: Business Transformation Manager.

Project: Business Transformation Project.

Project Management: It is an administrative and planning aspect of a *Project* and any other type of project where it sets the responsibilities, tasks and duties of the *Project*'s team members.

Scrum Master: It is not a traditional project manager, but a coordinator between the project team and the external world.

TOGAF: The Open Group's Architecture Framework.

The Business Transformation Framework and Its Business Engineering Law Support for (e)Transactions

Antoine Trad

Institute of Business and Information Systems Transformation Management, Switzerland

Damir Kalpić

University of Zagreb, Croatia

INTRODUCTION

In order to restructure the global economy in a sustainable manner, the integration of business engineering related legal standards is fundamental. Today, these legal standards are mature and can help in the transformation of traditional business environments to become a part of the newly interconnected global economy (Trad & Kalpić, 2014b). An important factor in continuously transforming a traditional business environment into an innovative and lean business engineering services oriented business environment are the roles of the Business Transformation Manager (BTM) and the needed business transformation framework. This framework is also needed to support the business environment's legal integration in the globalized environment. To achieve this legal support and integration, Critical Success Factors (CSF) must be used to legally assert, govern, automate, trace, monitor and control the Business Transformation Project's (BTP) artefacts. The CSFs can be used to manage the differences in business or (e)business local and international laws. Business environments must have the capacity to proactively and automatically recognize erroneous transactions, illegal activities, fraud and tax evasions (Trad & Kalpić, 2015a; Trad & Kalpić, 2015b; Trad, 2015b). A holistic legal assertion component for such projects is non-existent and is very complex to implement and an (e)system approach (or view) is suited for complex undertakings like the

integration and use of the Business Engineering Legal Assertion (BELA) component via the use of atomic building blocks and atomic solution blocks (Daellenbach & McNickle, 2005). In this research the focus is on the (e)transaction's legal assertion component that is a part of the this research project's control and monitoring module.

BACKGROUND

An BELA Component can be used in various business transformation and business engineering fields and this component is the main focus of this research phase. The BELA is a part of the Control and monitoring module (Cm). The Cm is in turn a part of the Selection management, Architecture-modelling, Control-monitoring, Decision-making, Training management and Project management Framework (SmAmCmDmTmPmF, for simplification in further text the term *Environment* will be used), that supports various aspects of BTP's activities. In this article the authors present a set of BELA managerial recommendations and a reusable pattern in the form of an (e)transaction legal support reference architecture (ISO, 2000; ISO, 2007; Trad 2015c; Trad c). The *Environment's* BELA must be synchronized through the architecture development method's phases, where each building block circulates through the architecture development method's phases. The building blocks contain sets of CSFs (Sugumaran

DOI: 10.4018/978-1-5225-2255-3.ch055

& Lavanya, 2014). These CSFs can be applied for: 1) the selection of the BTMs; 2) the implementation of BTP's architecture and modelling strategies; 3) the decision support system, in order to estimate the actual status of the BTP and to decide whether to stop or continue the on-going project (Gartner, 2013); 4) the control and monitoring engine with the needed BELA mechanisms; 5) the training needs of the BTP's team; and 5) the project management module's support.

A well-designed business architecture, as shown in Figure 1, must define (Analysing business, 2013): 1) the BTP's objective(s); and 2) a loose coupled BELA component that is a part of the control and monitoring system (Trad & Kalpić, 2015b). (e)Business or business engineering driven business environments refer to various types of businesses that are conducted using different types of avant-garde technologies, electronic media and services oriented technologies; where

the most common form is the business that makes its transactions and revenue via the web, using automation (e-business, 2014). In 2015, we can simply talk of plain business engineering, because many engineering artefacts like service oriented architecture, business process choreography have merged with business engineering fields; therefore there is a need for BELA robustness that is supported by the *Environment's* control and monitoring module, which covers the business engineering domain. The global research topic's and final research question (hypothesis #1-1) is: "Which business transformation manager characteristics and which type of support should be assured in the implementation phase of an business transformation project?" The targeted business domain is any business environment that uses: 1) internet and engineering technologies; and 2) frequent transformation iterations. For this phase of research the sub-question (hypothesis #3-4) is:

Figure 1. Business architecture's interaction with the environment
Source: Analysing business, 2013

“What is the impact of the business engineering legal support on (e)enterprise architecture and business transformation projects ?”

In this research phase the authors are targeting the BELA component's integration that as a part of the control and monitoring module and its influence on BTPs (Trad, 2015d). Actually there is a lack of awareness of business engineering integration that can hinder the financial status of business engineering oriented companies. This barrier for a successful BTP's finalization has to be handled. In this chapter the authors use industrial experiences made and lessons learned from surveying many enterprises. The surveys' outcome was that these enterprises are insufficiently informed about the impact of BELA laws that are applicable in business environment. Nearly half of these enterprises (45.8%) have responded and expressed this view. It seems that the problem lies in the current status of business engineering's related legislation and its integration. This integration can be considered to be a legal barrier and a BTP major issue. The BELA problems reported affect all parts of (e)transactions' execution process (Merriam-Webster, 2015). The vast majority of the surveyed enterprises expressed the importance of concluding a valid business engineering contract; the survey also showed that enterprises faced the following BELA problems related to (European commission, 2004):

1. The recognition of (e)contracts (39%).
2. The validity of (e)signatures (30%).
3. The recognition of (e)taxation (29%).
4. International provision of a (e)transactions by electronic means (27.5%).
5. The robustness of (e)payments (25.5%).
6. The efficiency of (e)marketing and advertising activities (25%).

These facts are fairly significant and they should be treated with caution because some enterprises which were surveyed are incapable to precisely identify the type of BELA problem they faced. That is why the automation of (e)

transaction's legal assertion becomes vital. The identification of BELA problems is usually considered to be of general nature and very difficult to localize and to be interpreted. Where, almost half (or 49.2%) of the encountered BELA problems are due to the huge volume of (e)transactions between enterprises. Insuring the BELAs should become the enterprise's strategic objectives and they should be treated in its strategic vision (European commission, 2004).

MAIN FOCUS OF THE ARTICLE

The BTM has to handle the complex and chaotic technical implementation phase of BTPs that are the major cause of very high failure rates (CapGemini, 2007; CapGemini, 2009). Therefore the implementations of Internet-based technologies and engineering resources in BTPs require specific (e)business and business engineering architecture strategy and real-world professional knowledge. For this specific goal the Institute of Business and Information Systems' Transformation Management (IBISTM) has developed: 1) a real framework; 2) education curriculum; 3) training programmes; and 4) certification programmes, to support BTMs and hence BTPs (IBISTM, 2015).

STRATEGIC VISION, PLANNING, AND GOAL(S)

Business engineering fields are very much related to (e)business models such as business-to-consumer (B2C) and consumer-to-consumer (C2C) and they need automated BELA components and control support to be insured against various types of bad intentions. By the year 2016, 40% of all business companies will standardize their governance, control and monitoring architecture; comparing this to less than 10% today; proves that the BELA's integration is a strategic goal for all BTPs (Kowall, & Fletcher, 2013). As shown in Figure 2, the BTM should be a member of the

company's strategic planning team and he should closely work with the company's legal team, where he can bring a view on changes in BELA regulations, control and governance integration (Trad, 2015b).

BUSINESS AGILITY

Business agility is achieved by combining various agility methodologies, using a bottom-up approach. The BTM can achieve an optimal business agility that can cope with local, national and international business engineering legislation constraints.

A Holistic Agile View

The BTM must achieve an agile holistic view on the BTP and that this agility is integrated in the enterprise's architecture development method through the use of various agile methods, as shown in Figure 3 (APMG international 2011; The Open Group 2014b). BELA components, risk and control compose the core of (e)enterprise's governance (ITGI, 2007; Tan & Carter & Toleman, 2009), where the integration of the BELA is integrated into the *Environment* using CSFs and business standards using agile methods.

Business Engineering and the Role of Standards

The research project uses technology and business engineering standards (OASIS, 2006) that include: 1) legislation and regulation frameworks; 2) enterprise architecture frameworks; 3) business process monitoring; 4) governance of processes and services; 5) business services monitoring; 6) agile standards; and 7) platform control and monitoring standards (Desfray, 2011; Cummins, 2010).

Business Engineering Service's Granularity

How granular should the related business services be and which types of atomic services should they contain BELAs, governance control and monitoring mechanisms, that all defined by the global architecture. These processes and services are classified into specialized repositories; a line of business services is a collection of similar business processes and services that should be classified in a corresponding categories in the BTP's repository. In order to have a successful unbundling process and hence a successful BTP, the BTM must integrate business services governance frameworks (Olson, 2008). Service oriented architecture governance focuses on the life cycle

Figure 2. Interaction between various parties in the global economy

Figure 3. Combining various agile techniques

Source: APMG international, 2011

Figure 4. The (e)business architecture phase

Source: The Open Group, 2014b; Hoidn & Schwidder, 2014

of a business service from its inception through modelling, assembly, deployment, management and eventually retirement (Trad & Kalpić, 2014c).

Business Engineering Services' Architecture

The business services' architecture and their BELA interfaces paradigm are based on the "1:1" concept.

This concept helps in achieving the assertion of: 1) the global business engineering concept; and 2) monitoring and integration activities. The BTM, or the enterprise architect, builds a prototype to define a template based on atomic building blocks. These building blocks contain BELA, control and monitoring mechanisms (Trad, 2015a). The outcome of the unbundling process is a bank of state-full atomic business services that can be as-

serted, controlled and monitored in real-time. In order to manage the agile and autonomic BTP's complexity in its implementation phase, an adequate assertion concept must be integrated in the architecture (OASIS, 2014). Such a concept is enabled by the establishment of a real world iterative model that can map all the BTPs artefacts in a linear "1:1" manner (The Open Group, 2014b).

(e)TRANSACTIONS

There is a need for a multi-end (e)transaction model that minimizes the dependencies between the various parties; where the (e)transaction connection is established between the consumer and the end supplier with minimal risks (Jin & Zhu, 2011). One of the most important CSFs that can be integrated and controlled in the BTP is the cost of (e)transaction ratio after and before the BTP completion. To calculate the cost of an (e)transaction there is the need to add-up the total cost of providing the business service and to divide it by the total number of successfully executed (e) transactions (Government Service Design, 2015). (e)transactions' management and outcomes have to be continually legally asserted, traced, reviewed, logged and their periodic summaries must be reported to the BTM and the enterprise's executive management (Fu & Mittnight, 2015).

(e)Transactions' Security Violations

Business environment's roles are orthogonal to security requirements, where the business environment roles define the responsibility for enterprise's resources. Management of the enterprise's legal interests, resources, governance, support, usage and reporting of access activity, should be managed by the BTM or the enterprise architect(s). In special cases, like the case of denial of request for access to sensitive business resources, it should be managed by the BTM. Thus the business environment's structure is an important consideration in the legal assertion, governing, control, access management and monitoring of (e)transaction's

security. The (e)transaction's security uses the following standards: 1) the policy framework (Oracle, 2015a); and 2) business messaging is needed for domain-specific assertion languages (Oracle, 2015b; OASIS, 2009). The regulation for the (e)transaction's security needs qualified time-stamps for robust (e)certification like: (e) seal, (e)signature, or other techniques (European Union, 2014).

(e)Transaction Law

From the business engineering point of view, the Uniform Law Commissioners promulgated the Uniform Electronic Transactions Act in 1999. It is the first adaptable effort to prepare an (e)law for business engineering and (e)commerce fields. Many countries and regions have already adopted business engineering standards to support these fields like, for example, the digital signature's legislation. The Uniform Electronic Transactions Act represents the first effort in providing some standardized rules to govern (e)transactions in (e) commerce. The Uniform Electronic Transactions Act rules are related to the Uniform Commercial Code, where the Uniform Electronic Transactions Act rules are primarily for (e)records and (e)signatures that are related to the execution of (e)transactions. An (e)transaction is composed of related actions that are executed between two or more end-points (The Uniform Law Commissioners, 2015).

LEGAL BASIS AND INTEGRATION

The evolution of business engineering forces various industries to implement BELA mechanisms into their business transformation frameworks. Such frameworks must incorporate (e)transactions legal collaboration with: 1) international; 2) national; and 3) local-regional laws and rules. Besides international and national laws, there are many legal frameworks, conventions, treaties and directives to be reviewed for the support of (e) system's (e)transactions.

The United Nations Commission on International Trade Law

The evolution of the Internet and service oriented technologies in business engineering has forced various global players to regulate all possible forms of (e)transactions (Wright, 1991). The exponential rise in the volume of (e)transactions has created a new dimension to this complex problem. The increasing numbers of (e)transactions in both international, national and local business engineering trade operations are achieved by means of (e)data interchange using wide means of communication technologies known as (e)commerce, which is a business engineering field. (e)commerce replaces the traditional business exchanges and replaces the classical paper-based exchanges in order to improve productivity and to enforce in real-time BELAs (Chissick & Kelman, 2000). This fact has motivated the United Nations Commission's push to establish the International Trade Law (UNCITRAL), which is a model of (e)law that supports various business engineering fields. This (e)law package is downwards compatible with all national and regional legal systems. The BTMs should be aware of various (e)law initiatives which define the rules for trans-border (e)commerce collaboration, that is crucial for an BTP. The BTP should accommodate all future legal issues and challenges in the future (e)system. Based on this fact, the BELA and rules integration must be adjustable, flexible, feasible and enforceable; this can be achieved by linking a legal act with a CSF. The *Environment* provides a BELA mechanism to wrap the existing national legal system and to be synchronized with current international (e)initiatives; taking into account the borderless nature of (e)transactions (The United Nations, 2004).

The European Union's (e)Commerce Directive

On the European commission's level, a legislation has been implemented to govern (e)commerce

collaboration, and an important progress has been done in the assertion of business engineering. European commission's member states have implemented and enforced business engineering related national practices (European commission, 2015a).

Business Engineering Legislation Assertion

The integration of the business engineering module is done with the use of the standardized legal environment of The Open Group's Architecture Framework. This legal environment supports data protection laws, contract law, procurement law, fraud law and many other legislation domains. The BTM and his team must design a pattern that links:

1. The initial business requirement, with
2. The applied business process model, with
3. The (e)transaction building blocks, with
4. The service level agreement, with
5. A well-defined set of (e)law articles and regulations to be respected by the (e)transaction, with
6. The possible set of legal risks, which are represented by a CSF.

As shown in Figure 5, the BTM and his team must have the needed set of skills to design a pattern that integrates various legislation topics.

Decision System's Integration and Risk Management

The *Environment*'s decision system delivers a set of possible solutions that determine BTM's skills and assists the BTP in solving various types of problems, such as possible legal pitfalls. The decision support can be also represented as an implementation of a business process model; such a solution is optimal because of the *Environment* BELA knowledge that can be stored in the (e) system (Trad & Kalpić, 2014d).

DECISION MAKING

Artificial Legal Intelligence

The *Environment* offers a heuristics based legal intelligence model to support legal reasoning mechanisms. The authors reviewed a number of systems that apply artificial intelligence for legal reasoning and have remarked that artificial legal intelligence model offered a holistic vision of (e) law, while a heuristics based legal intelligence model can offer solutions to BELA problems (Gray, 1997).

The Implementation

As shown in Figure 6, the *Environment's* applied BELA component feeds the decision making module that is based on an empirical problem-solving algorithm, with the needed success factors. The *Environment's* decision making module is specialized in the cases of problem solving and is based on a heuristics engine. The decision making module has an immense potential to improve the competitiveness of business engineering oriented enterprises; where it is an engine that enhances the BTM's ability to make decisions on selected (e)law issues (e-commerce, 2014). The *Environment* presents a new approach for decision support systems; where this approach can be applied by the modification and extension of existing

decision support system's basic CSFs (Sreka & Slaninova, 2012).

A BTM selection request or a specific BTP problem solving request can be fed in the form of CSF(s), into the *Environment's* reasoning model's root node and then the search process is launched to propose the optimal solution. The *Environment's* decision tree that is shown in Figure 6, is based on CSFs' mapping to BELAs' mechanisms; the mapping rules should be defined in the BTP's architecture vision.

Generated Events

Many events that are generated by the execution of an (e)transaction can affect the success of BTPs and the (e)system, therefore there is a need to capture and process all of them. The potential business impact on the BTP's (e)transactions legislation assertion must be assessed. Primarily, the costs related to BELA, control and processing can have an important impact on the all over costs of the BTP. Different BTP BELA techniques should be defined to ensure the accessibility to (The Open Group, 2014c): 1) consistent data; 2) credible (e)transaction information; 3) needed legal knowledge; 4) decision support for legislation governance; 5) monitoring; 6) analysis of logged data; and 7) planning. Information technology tools provide support for the planning and implementation of BTP's capabilities and legal control.

Figure 6. A view on the environment's tree solution nodes
Source: Trad, 2015c

Critical Success Factors

(e)transaction's trusted business information exchange that is enabled by the agreement of business partners, must be insured by a cohesive and coordinated interoperability framework. This interoperability framework should include the integration of the BELA environment, by the use of CSFs for linking various legal frameworks, standards, rules and agreements (European commission, 2015b). The *Environment's* BELA component uses the tracked information that is stored in the logging database. The stored information is filtered by using the CSFs that helps in analysing the Business Engineering environment to verify: 1) BELA violations; 2) performance; and 3) service level agreements' usage. The instances of business process models are tracked and the selected CSFs enable that the processes' filtered data are logged into the monitoring database. Business process models use CSFs to enable the management of certain types of historical data-patterns; these patterns are used in decision making process (IBM, 2015).

SOLUTIONS AND RECOMMENDATIONS

Proof of Concept

The proof of concept was built using the Microsoft Visual Studio; as shown in Figure 7, the proof of concept is based on the following facts:

1. It uses the research's *Environment* as a whole and its decision module.
2. The BTM and the BTP team members or the (e)enterprise's legal team, link legal constraints to specific (e)transactions' building blocks. This linking is done through the use critical factors to specific legal acts to be asserted.
3. The (e)transactions' model contains exception classes which check the legal constraints and if one or more of these constraints are violated, the (e)transaction is paused and warning messages are stored in the (e)system's log-server. The warnings are escalated to the support team.
4. The business engineering component scans the log-server for possible violations and if found, they are automatically reported to corresponding enterprise's department.

Figure 7. The (e)business legislation assertion's proof of concept
Source: Trad, 2015c

Critical Success Factors' Setup

Business interoperability is enabled by the use of CSFs' mapping. CSFs bind various legal acts, frameworks, standards, rules and service agreements (European commission, 2015b).

Process Models

The (e)transaction was prototyped using Sparxsystem's Enterprise Architect and Microsoft's .NET visual studio environments. The (e)transaction business process model uses web-services that make calls to the BELA class. The process model represents the relations between the (e)transaction's requirement, building block and an BELA process. As shown in Figure 8, the control and monitoring interface stays unchanged, whereas the logged data are interpreted differently to check business engineering violations.

FUTURE RESEARCH DIRECTIONS

The *Environment* future research will focus on a neural network based decision making module, which use a micro services concept.

CONCLUSION

The BELA component's holistic integration is an important factor for the business engineering environment's evolution and stability. In the past recent years, many industries have been implementing BELA solutions to proactively respond to probable legal problems and challenges. This research initiative is part of a long series of publications related to the business engineering architecture and business transformation projects. This research is based on mixed action research model; where the *Environment's* CSFs

Figure 8. The (e)business legislation assertion's process model

Source: Trad, 2015c

and managerial recommendations are offered to help (e)system's architects to decrease the chances to fail. A real world framework is offered. The most important managerial recommendation that was generated by the previous research phases was that the business transformation manager must be an architect of adaptive business system (Trad & Kalpić, 2014a). In this research phase and article, the focus is on how to integrate the BELA's component in a BTP. The used literature review sources and the *Environment's* proof of concept proved the feasibility of this research's phase and delivered the recommendations on how to implement a BELA component. The authors present the *Environment's* BELA list of managerial, architecture and technical recommendations that are sorted by their importance:

1. **This Phase's Proof of Concept:** Proved the research project's feasibility by implementing the proposed recommendations and an architectural pattern.
2. **The Role of Standards:** The *Environment* uses (e)law, architecture, technology and business engineering monitoring standards

(OASIS, 2006; European commission, 2004; European commission, 2015a).

3. **The BTM Must Deploy a Multivendor Strategy and An Anti-Locked-In Approach:** The BELA component must be designed by the BTP team and its implementation must be set as the company's strategic goal. To achieve this strategic goal, Availability and Performance Monitoring and the use of interfaces for Unified Monitoring Solution for the control of BTPs, must be implemented and linked to the BELA component (Kowall & Fletcher, 2013).
4. **The BTM's Basic Skills Should Encompass Knowledge of:** 1) Business Engineering and (e)commerce processes and the needed logging, monitoring and assertion architectures; 2) automated real-time BELA environments; 3) (e)enterprise or enterprise 2.0 architectures and implementations; and 4) governance integration.
5. **Use of Business Process Models:** Controlled and monitored business process models will enhance the management of legislation knowledge and will help also in the Business transformation project's implementation

- phase (Trad & Kalpić, 2013a; Birudavolu & Nag, 2011).
6. **Design and Implementation of a BELA Component:** For business transformation project there is a need to implement a BELA component that can be easily integrated with any framework or tool. The *Environment* is an applicable framework and the BTP should be supported by a configurable BELA component (IBISTM, 2015).
 7. **Decision and Governance Logs:** To manage BTPs, the team must implement an (e)system decision and governance logs management mechanism for the support of the Business Engineering environment.
 8. **Legal Intelligence, Decision Making Module and CSFs:** The decision-making module uses the BTP's logging system's database. The CSFs determine which BELA item must be checked and logged (Şeref & Ravindra & Ahuja & Winston, 2007).
 9. **Integrating Other Frameworks:** Operations', the Information Technology Infrastructure Library and other standard frameworks can be integrated in the BTP through the use of CSFs.

KEY TERMS AND DEFINITIONS

Business Engineering: It is the development and implementation of business solutions using business models to business processes and organizational structure.

CSFs: Can be used to manage the statuses and gaps in various project plans and gives the Projects the capacity to proactively and automatically recognize erroneous building blocks and to just-in-time reschedule the Project plan(s).

Environment: It is this research's framework.

Manager: Business Transformation Manager.

Project: Business Transformation Project.

Challenges of Meta Access Control Model Enforcement to an Increased Interoperability

Sérgio Luís Guerreiro
University of Lisbon, Portugal

INTRODUCTION

Today, countless access control models (ACM) solutions are available in the academy and industry. Nevertheless, the recognized development of ACM, in the majority of situations, these solutions specifies and implements the structural security access concerns of a single organizational silo (Sandhu *et al.*, 2000). Typically, ACM solutions are designed to fit and follow policies that are applied to a specific application layer of an organization. Early examples of such approach are the discretionary access control (DAC), mandatory access control (MAC), role-based access control (RBAC), time-role-based access control (TRBAC), Orcon or Chinese wall (Ferraiolo *et al.*, 2001; 2007).

Following this problem, Ferraiolo & Alturi (2008) raise the discussion about the feasibility of designing a meta access control model (MACM) fitting any specific ACM. So far, there are no bibliographic proofs that solve this posed problem. Moreover, Baker (2009) contributes to this discussion, stating the need to define a meta-ACM rather than specifying multiple instances in order to minimize the duplication of effort. Accordingly, to this author, the first goal to achieve in this endeavor is ACM conceptualization, and exemplifies it stating that RBAC is a particular instance of a MACM.

Moreover, recent advances proposed by Korman *et al.* (2016) show that the myriad of ACM solutions available difficult the management of IT models. Therefore, these authors propose an

ACM meta-model, designed in ArchiMate (The Open Group, 2013) to be used by the Enterprise Architects professionals. The meta-model is derived from the conceptual mapping of seventeen different ACM models. Then, ArchiMate relates the meta-model with enterprise concepts. In the end a unified meta-model for modeling authorization within enterprises is presented.

One the other hand, from a first sight, positioned in a different scientific field, interoperability is referred by Naudet *et al.* (2008) as “interoperability problem appears when two or more incompatible systems are put in relation”. In a broader sense, “Interoperability requirement is a statement that specifies a function, ability or characteristic, related to the capacity of a partner to ensure its partnership regarding compatibility, interoperation, autonomy, and reversibility, which it must satisfy” (Mallek *et al.*, 2012). Therefore, interoperability is considered as a key capacity to partners’ cooperation success (Patil *et al.*, 2007; Reul *et al.*, 2010). However, when two or more systems are interoperating, most of times, different ACM are in place and a barrier to the interoperation appears.

Therefore, given the context of ACM and interoperability, the following research question is logically raised: How to design and enforce a meta-access control model to facilitate the interoperability between different access control mechanisms?

For short, this paper assesses the possibility of using a meta-access control model to conceptual-

ize and instantiate many access control models. In specific, this research explores the following challenges:

- **Access Models Interoperability:** The paper uses a MACM to abstract all the concepts and relations contained in the many ACMs, and therefore creating interoperability between them.
- **Standardization of Storage for Access Data:** Standardization is realized through a single repository (and unique) for the MACM. When needed the MACM is instantiated for a specific ACM.
- **Provisioning of Access Models:** The MACM and ACM relationship enables the dynamic creation, reading, updating and deleting of access models, in order to adapt to the evolving organizational access requirements.

This paper has two-fold contributions: technological and societal. On the one hand, technological benefits are identified because of easier ACM implementation in each organization. On the other hand, societal benefits are related with lowering financial investments to interoperate the different organizations (*e.g.*: adaptive software enterprise resource planning (ERP) solutions between two small or medium enterprises).

This paper is organized as follow. Firstly, the research background is presented. Then, meta-access control model (MACM) is formalized. After that, solutions and recommendations are identified for the MACM. Then, future research directions are discussed. Finally, the last section concludes the paper.

BACKGROUND

Generically, a control system offers the capability to react whenever any disturbance affects the behavior of the controlled system or whenever a new reference is established (Guerreiro *et al.*, 2016).

Disturbance is assumed whenever the system is not producing the desired output for the imposed input. In these situations, the control system acts in the input, to change the controlled system's state.

Ferraiolo *et al.* (2007) defines that access control systems, or authorization in its broadest sense, is present in today's every information technology and is concerned with the ways in which users can access resources in the computer system, or informally speaking, with "who can do what". By these authors, access control is arguably the most fundamental and most pervasive security mechanism in use today. The author compares the actual access control models with the Guards, gates and locks that have been used since the ancient times to limit the individual's access to the valuables.

Nowadays, organizations use access control mechanisms to mitigate the risks of unauthorized access to their data, resources, software systems, etc. Each access request is assessed against a pre-defined authorization schema, and as a result, the access will be granted or denied. Several access control models exist to address changes in organizational structures, technologies, organizational needs, technical capabilities, and organizational relationships.

The standard NIST98 (Ferraiolo *et al.*, 2001; Sandhu *et al.*, 2000) is the most frequently used. It models the concepts for symmetric role-based access control (RBAC) to be used between the users, roles, permissions and constraints, as represented in Figure 1. It represents an evolution from the Discretionary Access Control (DAC) that grants access of individual object to individuals; Mandatory Access Control (MAC) and other policies due to less provisioning effort needed (Smith, 1997). Other known policies are different flavors of DAC, Time-Role Based Access Control (TRBAC), ORCON or Chinese wall. In RBAC the users are directly assigned to a role, each role has a set of associated permissions and changing the permissions affects the users associated with each role. Some well known constraints are separation of duties (SoD), conflict of interest (CoI), delegation of duties (DoD), binding of duty (BoD), least

privilege possible to the users, four-eyes-principle (2 tasks that must be executed by 2 users), history-based separation of duties (HsD). For example, the new constraints in the social networks: context constraints (Carminati *et al.*, 2009). The constraints are, in practice, applied to the relation between users/roles and roles/permission. Static constraints are offline computation and dynamic constraints are online computation. This model is applicable to organizational silos. However, it is limited to only one kind of organizational artifact, at a single time. NIST98 is broadly used in single architectural layers such as software applications or databases (Damiani *et al.*, 2002).

The RBAC model needs only to be made to role assignments, which are significantly fewer than individual assignments (Sandhu *et al.*, 1996). The RBAC model relies on user authentication, which in turn relies on identity management and defines relationships between the main concepts of Users, Roles and Permissions. RBAC's constraints restrict permissions depending on contextual information such as separation of duties (SoD) (Botha & Eloff, 2001).

ABAC approach, as proposed by Wang *et al.* (2004) extends the RBAC capability granting the

accesses to the artifacts based on the attributes possessed by the requester. The advantage when compared with RBAC is the management of the roles and permissions that is not needed. The access configuration is specified by a set of rules that uses the attributes that are issued in the client request. A change in the access policy is performed by a simple change in the rules. Kuhn *et al.* states that ABAC is still evolving from previous existing RBAC definition instead of emerging from new knowledge (Kuhn *et al.*, 2010). Moreover, the distributed nature of the web services and the service oriented architecture (SOA) environments are identified as a potential application area for the development of the ABAC concepts (Shen & Hong, 2006).

XACML 3.0 (2014) is a standard document that defines a RBAC detailed protocol for the structural part of the access control models. However, it does not allow SoD constraint. It includes Digital Signature Services, and a method for conveying and applying data access policies and controls. Complementary to the XACML, Security Assertion Markup Language (SAML, 2016) allows business entities to make assertions regarding the identity, attributes, and entitlements

Figure 1. Symmetric RBAC with dynamic separation of duties (SoD) constraint

Source: Adapted from Sandhu *et al.*, 2000

of a subject (an entity that is often a human user) to other entities, such as a partner company or another enterprise application. In practice, SAML is complementary with XACML, where XACML specifies and SAML implements.

Moreover, in the scope of federated and single sign-on, Shibboleth (2016) is an application example for allowing the definition of a single authentication mechanism. It is used by federated architectures of different resources (*e.g.*, web, pc client, etc.). The advantage of such approaches is the ability to implement identity management systems in a distributed environment. However, this solution only solves the initial user authentication process and does not include concerns with fine-grained access control to the artifacts.

Meta Access Control Model Formalization

This section introduces the problematic of using a single access control model. Afterwards, a formalization of a meta-model to solve this problem is prescribed.

Problem Definition

Figure 2 presents the classical approach for ACM enforcement. One ACM is chosen and an access control repository implements it by software. This approach is able to fine-grained control the artifact's access of a software system, usually, the entrance in the software system (*e.g.*, login). It is also noticed that ACM is most of the times, decoupled from the enterprise design. Besides being the root cause of interoperability problem, the practical consequences of this decoupling are: (i)

the duplication of effort in the control and models design counterparts and (ii) the designed models not aligned with control requirements.

Although, because of simplicity, this approach is highly used by the industry and a domain conceptualization is also offered by the ACM community (Ferraiolo *et al.*, 2007) to support a common conceptual understanding. The key terms and definitions presented in the end of this paper, represents the set of consistent terminology that is referenced as relevant concepts and that is used in the ACM industrial enforcements (and are used in this paper from this point forward).

On the other hand, when complexity rises the conceptualization is a usual intellectual tool to analyze and synthesize a set of concepts and their relations. Today, the connected, and digital, enterprises present a high level of complexity demanding new forms to represent them. In this rationale, a conceptualization has the benefit of sharing a common understanding of concepts between stakeholders with different backgrounds and understandings, as explained and exemplified in Gaaloul *et al.* (2014). One straightforward solution to visualize concepts and its relations is using the IHMC CMaps tool (Grandry, 2013). From an ontological perspective, the ACM concepts from Table 1 are the first step to obtain a full ACM ontology. Guizzardi (2007) distinguishes an abstraction and its representation, and their relationship with conceptualization and representation language. Additionally, in this line of research, Kühne (2006) presents a full study in regard the relationships between models, meta models and languages.

For the problem at hand, Figure 3 depicts ACM as an abstraction that, usually, is represented by an

Figure 2. Access control model definition and implementation, the classical approach

Figure 3. Meta access control model definition and implementation

access control repository (*cf.* Figure 2). Moreover, an abstraction is an instance of a conceptualization, in this paper proposed as a Meta ACM. By its turn, this Meta ACM is then represented by a Meta ACM repository. Finally, each access control repository is considered as a Model, which is an instance of a Meta ACM repository.

Therefore, our proposal is formalized by three stages: (i) the capacity to conceptualize a Meta access control model from a manifold of access control models (which are already implementation abstractions). Then, (ii) the representation of Meta access control model on a repository. Finally, (iii) the capacity to instantiate each access control model repository from the Meta access control repository.

SOLUTIONS AND RECOMMENDATIONS

This section identifies the challenges introduced by the previous section. Firstly, the proof of concept design is discussed, and then, the implementation challenges are discussed.

Proof of Concept Design Discussion

A proof of concept shows the applicability of a proposal within a specific domain. For exemplification purposes, a software system (an evolutionary prototype¹) to authorize queries on a graph database is considered. The objective of the prototype is to supply answers to queries formu-

lated in a previous provisioned graph composed by concepts and relations between the concepts. Before executing the query against the graph database the meta access control model components are responsible to check if the user is authorized.

The implementation follows the concepts proposed in Figure 3, where the ACM is supported by a XACML implementation. Then, MACM is specified using OWL. The consequence is that ACM is an instance of MACM. The OWL representation is then represented in a graph database to enforce the MACM repository (some alternatives are Neo4j (public available at <http://neo4j.com/>), orientDB (public available at <http://orientdb.com/orientdb/>), *etc.*). Afterwards, at run-time, when an access control mechanism is invoked, a transformation is applied to the MACM repository to implement the specific access control policy.

Implementation Challenges

Recalling the challenges posed in the introduction (i) Access models interoperability, (ii) Standardization of storage for access data and (iii) Provisioning of access models, this paper advances the following details as identified in proof of concept and summarized in Table 1.

FUTURE RESEARCH DIRECTIONS

As conceptualized in Figure 4, the meta access control model design, and supported in the biblio-

Figure 4. Meta access control model proof of concept

Table 1. The comparison between the challenges for access control models and meta-access control model

Challenges Posed	Access Control Models	Meta-Access Control Model
Access models interoperability	Casusically design with high level of implementation effort involved.	One model (MACM) supports all the access models, increasing the interoperability capability between organizations.
Standardization of storage for access data	ACM classical models do not encompass any type of standard between models.	Full supported. MACM supports an unique repository that is afterwards transformed into the desired ACM model.
Provisioning of access models	ACM classical models (namely the main standards) do not encompass any concern with provisioning. Each implementation needs to enforce its own provisioning mechanisms.	Similarly to ACM, the provisioning is also not specified. However, since MACM supports an abstract model, the provisioning follows a single provisioning mechanism.

graphic references, the following set of research challenges are raised:

1. *Implementing access control models (e.g., RBAC, DAC, MAC, ABAC, etc.) in XACML is still not consensual.*

XACML v3.0 (2014) Core and Hierarchical Role Based Access Control (RBAC) is the OASIS standard to enforce RBAC in XACML. The main challenges that are present in this standard are similar to the RBAC standard (Sandhu *et al.*, 2000): (i) the XML definition is verbose and complex; (ii) the interaction between the software systems specified in the standard are not industrial standardized; (iii) the policy administration, policy versioning, *etc.*, are not standardized; and (iv) the inability to enforce segregation (or by some literature is named as *separation*) of duties.

2. *How to design the mapping between XACML and OWL.*

This mapping problem is addressed by Finin *et al.* (2008a; 2008b). These authors identify a research thread of access control models defines as ontological models and exemplify the solution using RBAC. Two solutions are elicited: defining RBAC roles as OWL classes and a simpler approach defining RBAC roles as OWL values. As a result, the authors state that in the first solution: “the queries about a general class of access requests can be answered efficiently using a standard DL reasoner through subsumption reasoning”. However, both solutions have a problem with state change management due to the OWL monotonic nature. In practice, the role deactivations and role-permission assignment modifications must be performed outside the ontological reasoners.

Moreover, Helil & Rahman (2010) propose a solution to enforce RBAC XACML using OWL including the role hierarchy, the subject role assignment. To facilitate the RBAC policy definition and maintenance the OWL-DL is used.

3. *How to implement the correspondingly OWL into a graph database.*

Graph databases are derived from the scientific backgrounds of graph theory and mathematical logical and were firstly introduced around 1970 (Angles & Gutierrez, 2008). Despite the broad knowledge available from the last decades, it is recognized that recent advances in the scope of social networks has renewed its interest. Some examples of recent graph databases implementations are: Neo4j, orientDB, etc. OWL is a specification of a specific application domain written in a class/subclass oriented approach. The resulting graph database implementation could follow a schema definition or a schema-less approach. However, even in a schema-less approach, a simple definition of concepts and relationships are required. Therefore, when OWL is implemented into a graph database even a rudimentary schema is needed. The more refined is the graph database schema the more likely to fit the specific application domain, but the less applicable to similar applications. In the context of ACM, a balance between interoperability demand and support for many ACM models needs to be researched.

4. *How to transform MACM repository into an access control repository to be used at run-time by software application.*

From a non-ontological perspective, Hafeez *et al.* (2012) propose to use the SAML (2016) language to implement the interoperability using only the ABAC model. Consequently, this approach is only for the access models considered, and therefore, the solution is not scalable to others. With the same problem, De la Rosa Algarín *et al.* (2013) presents an implementation

of RBAC XACML using XML, in the scope of Health Level 7's Clinical Document Architecture and the Continuity of Care Record. Therefore, a wide-ranging solution for this problem demands a decoupling between the access control model itself and the capacity to store and interpret any access data. Recalling, Figure 3, the decoupling is designed by the MACM repository and its instantiation into a specific access control repository. For that end, the access control model needs to be referred in the instantiation event. Similarly, to an object oriented approach, when an object is instantiated with its specific data from a class.

5. *How to interoperate them?*

After all these identified research challenges, a question still remains, which is broader and is usually associated with, the management information systems scope (Laudon & Laudon, 2016). How is it possible to integrate into a unique enterprise system design all the previous four research items? In addition, how to use these concepts to enforce systems interoperability, considering the different technologies from disparate vendors that are in place? Moreover, how to enforce access control interoperability in organizational relationships that are semi-stable? From a lower abstraction perspective, the question of how to intersect data from different access control models stored in the same MACM repository is posed.

CONCLUSION

This paper addresses the context of access control models combined with interoperability between information systems. The research question of “*How to design and enforce a meta access control model to facilitate the interoperability between different access control mechanisms?*” uncover a complex problem demanding integrated efforts from different scientific areas, but where ontological design is proposed as a key competence to ground a future solution. In this sense, a meta

access control model design is experimented to systematize future research. Therefore, we identify the main challenges that are associated with bibliographic references identified.

To sum up, the challenges posed are related as follows: Access models interoperability, Standardization of storage for access data and Provisioning of access models. A full list of future work is presented in section future research directions.

KEY TERMS AND DEFINITIONS

Identity: Identity is the fundamental concept of uniquely identifying an object (person, computer, etc.) within a context. That context might be local (within a department), corporate (within an enterprise), national (within the bounds of a country), global (all such object instances on the planet), and possibly universal (extensible to environments not yet known). Many identities exist for local, corporate, and national domains. Some globally unique identifiers exist for technical environments, often computer-generated.

Object: Any resource accessible on a computer system, including files, peripherals such as printers, databases, and fine-grained entities such as individual fields in database records. Objects are traditionally viewed as passive entities that contain or receive information, although even early access control models included the possibility of treating programs, printers, or other active entities as objects.

Operation: It is an active process invoked by a subject. Early access control models that were concerned strictly with information flow (i.e., read-and-write access) applied the term subject to all active processes, but RBAC models require a distinction between subject and operation. For example, when an ATM user enters a card and correct PIN, the control program operating on the user's behalf is a subject, but the subject can initiate more than one operation of deposit, withdrawal, balance inquiry, or others.

Permission (or Privileges): They are authorizations to perform some action on the system. In computer security literature, the term permission refers to some combination of object and operation. A particular operation used on two different objects represents two distinct permissions, and similarly, two different operations applied to a single object represent two distinct permissions. For example, a bank teller may have permissions to execute debit and credit operations on customer records, through transactions, while an accountant may execute debit and credit operations on the general ledger, which consolidates the bank's accounting data.

Session: An instance of a user's dialog with a system is called a session.

Subject: A computer process acting on behalf of a user is referred to as a subject. Note that in reality, all of a user's actions on a computer system are performed through some program running on the computer. A user may have multiple subjects in operation, even if the user has only one login and one session. For example, an e-mail system may

be operating in the background, fetching e-mail from a server periodically, while the user operates a Web browser. Each of the user's programs is a subject, and each program's accesses will be checked to ensure that they are permitted for the user who invoked the program.

User: Refers to people who interface with a computer system. In many designs, it is possible for a single user to have multiple login IDs, and these IDs may be simultaneously active. Authentication mechanisms make it possible to match the multiple IDs to a single human user.

B

ENDNOTE

- ¹ An evolutionary prototype is a software system that has the ability to support new developments. In the opposite, a disposable prototype is only used to requirements validation and do not have the ability to support new developments.

Cognitive Ergonomics in 2016

Ronald John Lofaro

Embry-Riddle Aeronautical University, USA

INTRODUCTION

Cognitive Ergonomics deals with, amongst other areas, decision-making, skilled performance(s) and training. This chapter will briefly explicate what began, 30 years ago as a cognitive task analysis (CTA) for identifying critical skills needed for skilled performance, with decision-making involved in every step. Over the years, it evolved into a Delphi paradigm that extended far beyond a CTA. With the advances in technology, especially communication technologies, some of this paradigm has re-emerged in what are termed Estimate-Talk-Estimate (ETE) Delphi efforts. This Chapter will show how to integrate the elements of the paradigm cited above with elements of Pareto Analysis and ETE. The resultant model uses today's technology to achieve extremely accurate results across many venues. Thus, this Chapter is a natural progression/extension of the author's Chapter entitled "Knowledge Engineering: A Methodology and Examples" (Lofaro, R.J., 2013) in the 3rd edition of *The Encyclopedia of Information Science and Technology* (2014). In that Chapter the author presented both the Small Group Delphi (Lofaro, 1992) as developed and expanded over the years and the newer Estimate-talk-Estimate variant of the Delphi process. At that point, elements of both Delphi processes were blended to produce an initial look, with some methodological avenues, for use in a paradigm in tune with the tremendous speed, instantaneity and scope of today's technological advances in communication. This Chapter will take that rough template and integrate it with elements of Pareto techniques, to initially identify and sharpen criticality of possible problems/solutions of issues. The selection and the rationale for the selection

of the elements of both the Pareto analysis and for the elements of the SGDP will be explicated. At that point, the new Pareto/SGDP/ETE process could be implemented to achieve guidelines for achievable resolution of a variety of problems requiring accurate decision-making. The decision-making will be of a distributed nature, enabled by computers and the Internet. Further, this Chapter will examine three current, problematic areas and outline how this now tri-partite paradigm can be used on these areas to show how decisions can be made on standards, policy and training needs

BACKGROUND

Knowledge engineering (KE) has been defined as follows: "...an engineering discipline that involves integrating knowledge into computer systems in order to solve complex problems normally requiring a high level of human expertise." (Feigenbaum and McCorduck, 1983). For a succinct overview of KE, see Studer, Benjamins and Fensel (1998). Knowledge engineering is also linked to cognitive science and socio-cognitive engineering where the knowledge is produced by socio-cognitive aggregates (mainly humans); this was one rationale for the SGDP. A newer term, cognitive engineering (CE), includes mental workload, decision-making, skilled performance, human-computer interaction, human reliability, work stress and training as these may relate to human-system design. There is not only great overlap with KE but, almost an isomorphism. Therefore, CE has mainly replaced KE as the term used in such efforts. Cognitive Ergonomics deals with decision-making and focuses on the fit between human cognitive abilities and limitations and the task. As such, it can be

DOI: 10.4018/978-1-5225-2255-3.ch057

viewed as a portion of a Venn diagram Universe that includes Cognitive Engineering, again with definite overlapping.

Delphi Processes

A subset of CE is the Delphi technique/process. Traditional Delphi techniques include anonymity of response, multiple iterations, convergence of the distribution of answers and, a statistical group response (Judd, 1972). A seminal paper on the Delphi process was written by a then-Rand Corporation employee (Brown, 1968) and may be available from Rand or from American Society of Tool and Manufacturing Engineers (ASTME), *now known as Society of Manufacturing Engineers*. It would seem clear that Cognitive Ergonomics can avail itself of Delphi processes

The Small Group Delphi Paradigm

A modification to Delphi processes is the small group Delphi paradigm (SGDP). The SGDP took the Delphi process in another direction by modifying it via merger with elements of group dynamics in order to have interactive (face-to-face) Delphi workshops. The development of this modified Delphi, the SGDP, involved the merger of a specific knowledge engineering technique (Delphi), with Fleischmann's theories of underlying abilities (Fleishmann and Quaintance, 1984; revised 2000) and some principles of group dynamics. This modification resulted in a paradigm for using small groups of subject matter experts (SMEs) for any project that requires that a set of SMEs be used to identify, evaluate, and critically rank tasks (an extended and enhanced task analysis), identify core needs/skills, recommend modifications to equipment, procedures and training. Finally, the SGDP can be used to sharpen, modify and revise existing methodologies. Thus, traditional Delphi processes were modified into a new paradigm (Lofaro, 1992). This effort and the subsequent use (Lofaro, Gibb and Garland, 1994; Gibb and Lofaro, 1994; Lofaro, 1998, 1999) of the resultant

paradigm, SGDP, in other, varied venues have produced both new modifications to the SGDP and highly accurate data that were operationally implemented. The extensions of the paradigm indicated that it had an applicability over many domains. These many SGDP efforts also resulted in sharpening, modifying and revising the original methodology. That the core SGDP has been used in many environments demonstrated a robust flexibility and generalizability of the paradigm. As Meister (1985) had noted, "The (Delphi) methodology is by no means fixed...[it] is still evolving and being researched." This is as true now as it was when Meister stated it. In point of fact, with the leaps in communication methods and related technology, even more so.

CURRENT ADVANCES IS DELPHI PROCESSES AND A NEXT STEP

The use of face-to-face Delphi techniques has been re-discovered. It is important to state that, circa 2005, the use of face-to-face groups in a Delphi has now become accepted. New technologies have resulted in what are generically referred to as mini-Delphi or Estimate-Talk-Estimate (ETE) with many variations. Other innovations come from the use of computer-based (and later web-based) Delphi conferences. One example of a difference in a type of ETE (a computer-based Delphi) versus either a traditional or SGDP Delphi is the iteration structure used in the traditional or SGDP Delphis, those iterations which are divided into three or more discrete rounds, can be replaced by a process of continuous (roundless) interaction, enabling SMEs to change their evaluations at any time. As Bolognini (2001) has said, the involvement of a large number of participants, the use of two or more panels representing different groups (such as policy-makers, experts, citizens), which the administrator can give tasks reflecting their diverse roles and expertise, and have them interact within ad hoc communication structures: these are strengths of computer and web-based ETEs. The

reader is referred to the work of Turoff and Hiltz (1996) on computer-based Delphis.

While the author was heartened to see his seminal concepts (the coupling of traditional Delphi methods with group dynamics and face-to-face sessions) have become accepted, a question arose: What now? The author believes that another process for analysis needed to be front-loaded into any SGDP/ETE; elements of a Pareto analysis. That is to say, the author believes the next step is to combine elements of a Pareto technique at the front end of an SGDP/ETE process, resulting in a new paradigm. The questions to be answered are which elements of Pareto analysis are to be used (with rationale) as well as which elements of a SGDP are to be incorporated, again with rationale? We already have ETE-type Delphis done using web sites where the process is conducted in real-time. The ETE type would not involve selecting elements thereof but would be chosen on the basis of what data came out of the Pareto/SGDP. Re-stated: As to which type of ETE would become part of this new paradigm, that is dependent on what elements of the Pareto and SGDP are to be part of the new paradigm. Lastly, a demonstration will be given of how this new model would be applied to current, real-life problems in three very different venues

What Are the Elements of a Pareto Analysis to Be Used and Why?

The Pareto would be step one because it would identify problems, then, sharpen (focus in on the ones that are amenable to resolution) while, at the same time, providing an ordering of which should be worked on via criticality ratings. The elements of a Pareto analysis would be the first three steps in such an analytic technique. Step 1: Identify and list problems to be examined. Or, if and only if one problem/issue exists, a break-out of the sub-problems could be done. Step 2: identify causal factors inherent in each problem. Step 3: Score (in this case, criticality rate) the problems. The Pareto, done in the context of a SGDP/ETE could also allow for many possible solutions to be

evaluated by many types of SMEs with differing areas of expertise but areas germane to the problem. This would result in a winnowing down of courses of action to those that were realistic and possible of success. The advantages of using a Pareto, SGDP and an ETE (all computer/Internet driven) are that they are all content-area neutral and, in a real sense, generic in application.

What Core Elements of the SGDP Are to Be Used and Why?

Briefly, what are the core elements of a SGDP and which should be/can be used in an ETE Delphi that is computer-based and web-driven? Additionally, why are these particular core elements selected? What follows is a very short synopsis of SGDP core elements because of space constraints. For a more complete SGDP write-up, email the author; *lofaro@msn.com*.

1. **SME Selection:** Identify the best SMEs for the SGDP Workshop.
2. **The SGDP Objectives:** Develop the objectives and sub-objectives so that all the components needed to achieve the whole objective will be in place.
3. **The Read-Ahead Package:** It must be prepared and sent to the Workshop participants at least three weeks in advance; longer if there is time. The read-ahead should include: purpose and rationale for the workshop, the use-value of the data generated by the SGDP workshop; the objectives of the workshop and, any longer-range goals that the workshop will enable; [a clear statement that small-group processes will be used and that group dynamics training will be the first step in the process---and that a trained, experienced facilitator will be doing this training and will be on-site for the duration along with a "homework" assignment to be completed and brought to the workshop. Finally, included is a day-by-day Agenda of sorts.

Along with the read-ahead, a complete set of protocols is to be completed and given to the participants when they arrive.]

4. **The SGDP Process:** Upon participant arrival, proceed with instructions and exercises in group dynamics, “groupthink,” functional/dysfunctional groups and a definition/example of real consensus.

Simply put: Numbers 1,2 and 3 along with a definition/example of real consensus. As to Number 3, the portion in parentheses does not apply. Note that 2 and 3 essentially only one component; doing 3 incorporates 2. These elements were selected because they can apply to any problem/issue and would be the foundation of any Pareto/SGDP/ETE.

General Methodology for Pareto/SGDP/ETE

All participants can be logged on simultaneously, each participant can briefly state their name and credentials, the group dynamics instruction can be done by the facilitator to all simultaneously (aside: it would seem that a linked network of all SMEs is possible and even *de rigueur*. This will allow for instant feedback by any SME during a session, as well as discussions). The iteration structure used in SGDP, which is divided into as many discrete rounds as needed for consensus, can be replaced by a process of continuous (roundless) interaction enabling SMEs to change their evaluations at any time and give a rationale with ensuing discussion in real-time. Finally, the statistical group(s) response(s) can be updated in real-time and shown whenever a SME, or a group, provides a new evaluation. It is clear that “face-to-face” discussion will be virtual. This is, to the author, a real and significant loss. But, the speed, multiple iterations, real-time, access to a large number of SMEs and other aspects to be gained cannot be ignored. Another possible modification is a multi-tiered Pareto and then, SGDP where

the use of two or more groups working different problems can be convened and given objectives based on their expertise. As these groups come to consensus on their objectives, these new data can be integrated, built into a new re-ahead package and made available to a new SGDP set with new or prior SME’s

EXAMPLES OF USING AN SGDP/ETE WITH PARETO TECHNIQUES: 2016 AND BEYOND

An initial thought, with the author’s background in education (mathematics degree; taught mathematics and math ed) was the current and it seems now controversial United States federal Common Core Standards. While these Standards were federally developed (actually done under contracts), the States were to develop (or not) curricula based on these standards. One set of issues seem to revolve around whether the Common Core Standards are an attempt by the federal government, through federally-funded interstate consortia assessment entities, to make the States hew to the Standards. This would make the Standards, *de facto*, mandatory at the State level. Another issue is the critiques of the Standards themselves, especially it seems the Mathematics and English ones, by educators, scholars and parent interest groups. At the federal level, it seems the Standards are a *fait accompli*, thus precluding any Pareto/SGDP/ETE efforts. However, at the State level, such Delphis could help in analyses of the Federal Standards; development of State curricula and pedagogy for teaching the new State curricula.

Such an effort would involve multiple subject area-specific groups, each composed of educators (classroom teachers as well as University teacher education professors), parents and some legal experts. The goal would be a State-wide curricula, with assessment techniques designed to both accurately evaluate student progress and needs as well as pass muster with the Smarter Balanced Assessment Consortia (SBAC) and the Partnership for

Assessment for Colleges and Careers (PARCC); these are the federally funded assessment consortia mentioned above. While this seems to possibly be a moot effort as there are federal Standards, some States (Oklahoma, Texas, Virginia, Alaska, Nebraska and Indiana) have already indicated they will not use the federal Standards and Minnesota will not use the federal Mathematics Standards. So, it seems that such States might support such Pareto/SGDP/ETE efforts.

The author selected, as another exemplar, the aviation field in which he worked for over 22 years: What are some current 2015 aviation issues (as well as prior but unresolved ones) that are both vital to aviation safety and amenable to some form of the Pareto/SGDP/ETE?

In view of current and recent fatal accidents, a look at air carrier upset training may be fruitful. Such training was brought to the fore by the Colgan Air accident with 50 fatalities. There was the Air France flight 447 (229 lives lost) in which the pilots did not recognize that they were in a high speed, high altitude stall; these accidents led to some attention/training being devoted to this issue. We now have AirAsia flight 8501, crashed with 162 souls on board and Malaysia flight MH 370, still unfound with 239 lives lost. At least the AirAsia flight may be a scenario similar to the Air France accident.

In direct response to the Colgan crash, Congress passed the Airline Safety and FAA Extension Act of 2010, which mandated that the Federal Aviation Administration (The FAA regulates aviation in the USA, from air traffic to civil aviation security, the operation of air carriers, pilot training and more) require pilots to complete 1,500 flight hours before they're allowed to fly commercially, up from just 250 hours before the act. This new rule may do little to improve safety. Both pilots involved in the Colgan crash had far surpassed 1,500 hours of flight time, so that requirement probably had little to no impact on the accident. However, the FAA, while not yet issuing an Advisory Circular (AC) or a Federal Aviation Regulation (FAR), has issued a document called Airline Upset Recovery

Training Aid, version 2. There seems to be some problems with using a hexapod/full-motion flight simulator (FS) that will be part of an expected FAA pilot training rule by 2018 (Croft, John. 2014a). There are also issues about in-aircraft training and swept wing jet aircraft specialized training. There is some controversy also involving the American Airlines UPRT ground school with FS training, called advance aircraft maneuvering program (AAMP). This training was seen by The National Transportation Board (NTSB) as possibly a contributing factor in the American Airlines flight 587/A300-600 crash in November, 2001 (Croft, John. 2014b). The area outlined may seem fruitful but it is fraught with regulatory and legal problems. That having been said, since the upset training is in the FAA rule-making arena, any Pareto/SGDP/ETE efforts would probably be moot, albeit both germane and instructive. Yet, there seems to be a definitive need for such efforts. However, we go to another problem area which may be more amenable and less encumbered.

A second problem area is of long standing and, has been often researched: flight crew fatigue. Fatigue from flying has been an issue since World War I, yet no resolution has been found. A fairly recent example is the United Parcel Service (UPS) flight 1354 crash in Birmingham, Alabama, in late 2013. At this time, it seems that the UPS pilots, NTSB and Airbus (the type aircraft involved was an Airbus A300-600), are in, to put it mildly, some disagreement as to causation. Remember that UPS has an FAA-managed aircrew fatigue risk management program (Croft, John, 2014c). If memory serves, (the author was with the FAA at the time), the FAA, the National Aviation and Aerospace Administration (NASA) and United Air Lines were involved in a study on the fatigue effects of flying "long haul," Trans Pacific flights; these were sometimes 15 or more hours long. As one result, the FAA proposed a draft AC called Controlled Rest on the Flight Deck; the aircarrier industry opposed it and it was shelved. Here we are, in 2015/6 and aviation still is working on this issue while lives are being lost.

Thus let us look at aircrew fatigue. What would be the design and process for a SGDP/ETE to work this safety issue?

The SME's must include, in the main, current aircarrier pilots; both U.S. flag-carriers and regional air carriers pilots must be in any/every working group. The goal of such an effort would be to develop a set of recommendations for an FAA FAR on dealing with aircrew fatigue as a recognized safety problem, with rationale. The FAA rule-making process is long and complex. It does have methods for aviation industry input as well as aviation industry objections/agreement. With that in mind, each group in this effort must have an FAA attorney as a member. The material for every group should include accident investigation data (for the prior 30 plus years) where aircrew fatigue was identified as a causal or contributing factor. This would also entail having an NTSB accident investigator/analyst on each group. The general mythology to be used has been shown in a prior section.

Another seemingly obvious candidate for the SGDP methodology is Operational Testing (OT); specifically OT&E (Operational Testing & Evaluation). The goal of any OT is to determine the system's capability to perform its mission in the operational setting and to both determine and evaluate core operational effectiveness and suitability problems (Maliko-Abraham, Helene and Lofaro, R.J., 2003). Operational tests and evaluations are conducted on production, or production-representative articles, to determine whether systems are operationally effective and suitable. Such testing entails operational testing of production representative test articles and uses typical operational scenarios that are as realistic as possible. It is here that the Pareto/SGDP/ETE can be modified so that SMEs can use it in OT.

Dumas and Redish (1999) indicate that to be a good OT testing scenario, it needs to be short, developed in the end-user's terminology and, so clear that all participants using the scenario will understand it. A small set of carefully selected

SMEs would be used to face-validate the existing scenarios. This SME set also would ensure that all the necessary operational issues were embedded in the scenarios. A second group of SMEs would also assist in the test sequencing as well as the techniques/scalings to be used in workload analysis. While the process of multiple SGDP workshops may seem lengthy, it is not the case. The SGDP/ETE sessions would run consecutively, each new one beginning with the data from the prior one--and each session should need approximately 4 days to complete. The experience and insight as to the realities of the operational arena of the SMEs are both needed and invaluable. Upon completion of the actual OT, all SME members of the two previous sessions would be convened to interpret the results and to make a set of recommendations. These recommendations may include retrofit, modification, and training. The two SGDP groups would work independently at first. Then, as they finished, they would convene into one group to finalize their results.

FUTURE RESEARCH DIRECTIONS

The Future Research Directions are close to the Conclusions, being inter-twined: the tri-partite model shown above needs to be implemented; perhaps as a University or think-tank project... even as a government (at some level) one. The results, pro or con, need to be published and, as always, suggested modifications need to be listed, with rationale, for any future work.

CONCLUSION

The tri-partite model explicated above, with exemplar uses, offers significant advances in diversified, accurate decision-making needed over a broad spectrum of problem areas; defining and explicating standards as well as the training needed to achieve resolution.

KEY TERMS AND DEFINITIONS

(United States) Common Core Standards (Initiative): The Common Core State Standards Initiative is an educational assembly in the United States that details what K-12 students should know in subject areas focused on English language arts and mathematics at the end of each grade. What has been produced is a set of standards by subject and federal government will fund states to incorporate these standards into teaching curricula. This has begun to draw criticism and generate controversy as a method of federal control of education.

Domain Expert: A person with special knowledge or skills in a particular area of endeavor. The term *domain expert* is frequently used in expert systems software development.

Estimate-Talk-Estimate (ETE) Delphi Process: Any Delphi process is based on the principle that forecasts from a structured group of experts are more accurate than those from unstructured

groups or individuals. The technique has lately been adapted for use in face-to-face meetings, and is then called mini-Delphi or Estimate-Talk-Estimate (ETE) Delphi.

Group Dynamics: The interactions that influence the attitudes and behavior of people when they are grouped with others through either choice or accidental circumstances. Social psychologist Kurt Lewin coined the term *group dynamics* to describe the positive and negative forces within groups.

Groupthink: Groupthink, a term coined by social psychologist Irving Janis (1972), occurs when a group makes faulty decisions because of group pressures; groupthink is a psychological phenomenon that occurs within a group of people, in which the desire for harmony or conformity in the group results in an incorrect or deviant decision-making outcome.

Pareto Analysis: A technique used for decision making based on the Pareto Principle, known as the 80/20 rule. It is a decision-making technique that separates a limited number of input factors as having the greatest impact on an outcome, either desirable or undesirable. In its simplest terms, Pareto analysis will typically show that a disproportionate improvement can be achieved by ranking various causes of a problem and by concentrating on those solutions or items with the largest impact. This type of decision-making can be used in many fields of endeavor, from government policy to decision-making.

Small Group Delphi Paradigm (SGDP): A variant Delphi model based on traditional Delphi processes, as developed and refined from 1985 through 1992 by the author. Its core features are multiple face-to-face sessions of small groups of carefully selected SME's, always with a facilitator and a step- through set of iterations to achieve consensus, not statistical sharpening.

Subject Matter Expert (SME): An individual who exhibits the highest level of expertise in performing a specialized job, task, or skill within the organization.

United States Federal Aviation Administration (FAA) Advisory Circulars (AC): The FAA normally publishes advisory circulars (ACs) designed to provide assistance and guidelines in complying with FARs; they serve as a “how to” template. The AC’s are titled and numbered and are not legally binding.

United States Federal Aviation Administration Regulations (FAR): All are in the Combined Federal Regulations (CFR), Title 14, Aeronautics and Space; each a descriptive title and number; they are legally binding.

Corporate Social Responsibility

B**Ben Tran***Alliant International University, USA*

INTRODUCTION

In today's changing world, Corporate Social Responsibility (CSR) is a growing area of interest for academics, practitioners and entrepreneurs, in terms of both theory and practice. CSR is a concept whereby companies integrate social, environmental, and health concerns in their business strategy (policy) and operations and in their interactions with stakeholders on a voluntary basis. The social responsibility of business encompasses the economic, legal, ethical, and discretionary expectations that society has of organizations at a given point in time (Carroll, 1979). As the world is shrinking due to globalization the concept of CSR has acquired an undeniably high degree of relevance and scope in a large number of sectors. Many academicians and practitioners are developing theory and practices of this concept of social responsibility among entrepreneurs.

An examination of the literature of CSR and corporate reputation has led to the rise of stakeholder management in a complex market environment in the United States, Europe and Asian regions. Today's corporations have paid substantial attention to the three key concepts, corporate reputation (CR), corporate social responsibility (CSR), and stakeholder relations (SR) (Argenti & Barnes, 2009; Argenti & Druckemiller, 2004; Cees, Riel, & Fombrun, 2007). In an Asian country, many corporations such as multinational corporations (MNCs), government linked corporations (GLCs) and local private companies (LPC) eagerly communicate with their internal and external stakeholders to portray the unique identity of the organizations (Abdullah, 2007). By having a unique identity of the organization, the corporations not only can improve the

image and reputation of the organization but also differentiate its strategy development and shape the extraordinarily valuable asset of the organization (Bouchokhi & Kimberly, 2008).

There are numerous studies (Balmer & Greyser, 2003; Fombrun & Riel, 2004; Kitchen & Schultz, 2001; Cees et al., 2007) and increasing debates concerning image, identity, and reputation with the greater emphasis on how the organizations managed their communication systems. Some studies also attempt to focus on corporate branding which is substantially associated with managing reputation of MNCs in a Western country (Money, Rose, & Hillenbrand, 2008; Hatch & Schultz, 2008). However, a few studies in an Asian country (Lines, 2004; Moon, 2005) were found to examine corporate reputation focusing on stakeholder relations and corporate social responsibility. A "West is best mentality" can be daunting thought but it affects a real attitude among Asian society. Chinese consumers downgraded Chinese-branded companies and rated higher reputation to international companies such as Nokia, Intel, BMW, and IBM (Fombrun & Pan, 2006, p. 165). Within this context, one frequently asked question is: What theory or model should be followed or considered for implementation of CSR practices?

BACKGROUND

The days when corporate social responsibility (CSR) was a concept and practice confined to North American and European companies are over. Particularly in the past ten years or so, Asian businesses have increasingly brought to bear their considerable energy and thought to matters of regional and global concern. From climate change

DOI: 10.4018/978-1-5225-2255-3.ch058

and other sustainability questions to product safety and global labor standards, Asian business leaders have an opportunity to shape the international response to some of the broad issues facing global society. Not only will Asian business leaders who embrace corporate social responsibility offer their own distinctive approach, but their participation in sweeping worldwide matters can have far-reaching and beneficial impact for all.

Literature Review

The impact of CSR on corporate reputation is shaped by how the firm communicates its CSR activities to its external stakeholders and how its activities are reported in the national media and other communication mediums (Rettab, Ben, & Mellahi, 2008). McWilliams and Siegel (2001) emphasized that consumers consider socially responsible firms to have a good reputation by constantly executing a series of programs of social responsibility. Such CSR programs give a big impact to corporate reputation. A good reputation influences a positive consumer satisfaction. In addition, companies use CSR communication to enhance customer loyalty (Abdullah & Aziz, 2011; Jacob & Kyner, 1973; Keller, 1993). This effort may improve favorable relationships between the organization and its stakeholders. As Grunig and Hunt (1984, p. 6) stated that effective public relations is about “management of communications between an organization and its publics”.

McWilliams and Siegel (2001, p. 120) pointed out that positive CSR, “creates a reputation that a firm is reliable and honest”. Similarly, Bhattacharya and Sen (2004) argued that CSR builds a reservoir of goodwill that firms can draw upon in times of crisis. Positive reputations have often been linked with positive financial returns, with their value tied to the inability of competitors to imitate the reputation. Roberts and Dowling (2002) found that the value of a positive reputation is, “precisely because the development of a good reputation takes considerable time and depends on a firm making stable and consistent investments

over time”. Therefore, reputation is arguable the most valuable asset of any firm and thus worth protecting. Banerjee, Iyer, and Kashyap (2003) postulated firms that are under greater scrutiny from a broader stakeholder groups facing greater business exposure.

In addition, Post, Lawrence, and Weber (2002, p. 8) found that stakeholders is “those people and groups that affect, or can be affected by an organization’s decision, policies, and operations”. Øyvind Ihlen (2008, p. 136) from his research indicated that the organization’s success depends on how it is able to manage its relationship with key stakeholder groups, such as customers, employees, suppliers, communities, politicians, owners, and others. Similarly, Werther and Chandler (2006) quoted that the stakeholder relationship occurs as a consequence of business activities and such groups might be local communities, the media, business support groups, state and local government, social activist groups and so forth. To ensure the organization’s success, the company have “to keep the support of all these groups, balancing their interest, make the organizations a place where stakeholder interests can be maximized over time” (Freeman & Philips, 2002, p. 333).

According to Abdullah and Aziz (2011), however, defined CSR as a business approach that creates long-term shareholder value by embracing opportunities and managing risks deriving from economic, environmental and social developments. Business in the Community (BITC) defined CSR as “a company’s positive impact on society and the environment through its operations, productions or services and through its interaction with key stakeholders such as employees, customers, investors and suppliers” (Katsoulakos & Katsoulakos, 2006, p. 13). On the other hand, Carroll (1979, p. 500) states that businesses that practice social responsibility attend to “economic, legal, ethical, and discretionary (philanthropic) expectations that society has of organizations at a given point in time”. Hence, the CSR concept relates closely to its family terms such as corporate citizenship (Bowen, 1953; Carroll, 1979; Mason,

1960), corporate social responsiveness (Ackerman & Bauer, 1976; Frederick, 1998; Strand, 1983), corporate social performance (Stanwick & Stanwick, 1998; Swanson, 1995; Wood, 1991), and stakeholder management (Donaldson & Preston, 1995; Jones, 1995). Following to the notion of CSR quoted by McWilliams, Siegel, and Wright (2006, p. 1), organizations should not only be concerned about making a profit but also engaged in “actions that appear to further some social good, beyond the interests of the firm and that which is required by law”.

However, the concept of CSR is still blurred and fuzzy argued by Lantos (2001). Vaaland and Heide (2005) decomposed CSR into CSR enforcement—the ability to make the firm more resistant to be attacked for sudden, unforeseen and negative incidents highlighted by anger stakeholders. This may threaten and could seriously harm the company’s reputation. On the other hand, if the critical incident is handled skillfully, under CSR recovery—the potential loss of company reputation could be minimized and possibly recovered after a short time (Vaaland & Heide, 2005, 2008). Studying on CR, CSR, and SR are often associated with improving the organizational performance. Those recent and past studies have proven the strong alignment between CR, CSR, and SR within the Western hemisphere. The fact that the emerging concepts are universal, which means they are widely recognized in the U.S., Europe, and Asia. However, there is no universal definition of CSR as the concept has been defined differently in different countries.

Corporate Social Responsibility (CSR) in Asia

Corporate social responsibility (CSR) in Asia, however, has to be seen not only as philanthropic activities of the firm on the one hand but also as initiatives beyond legal requirements in the other (Ramasamy, Yeung, & Au, 2010). Such definitions of CSR are prevalent in CSR literature from western developed countries. Hemingway and MacLagan (2004), for instance, argue that

the social responsibility of firms is one that is voluntary and goes beyond the law. This may implicitly assume that companies are already ethical and lawful. This assumption, however, cannot be taken for granted in developing countries where the rule of law is relatively weak. Thus, companies that adhere to legal manner have to be considered to be socially responsible businesses as well. For this reason, Carroll’s (1979) definitions of SR is perhaps among the most suitable description. Carroll’s pyramid-like model explains the various responsibilities of businesses, building on economic responsibilities and later moving onto legal, ethical, and philanthropic responsibilities in a stage like manner.

CORPORATE SOCIAL RESPONSIBILITY (CSR) WITH ASIAN CHARACTERISTICS

While sustainability is essentially a global concept, CSR has developed differently in different parts of the world. This is not surprising, because CSR flows naturally from the social contract that defines the relationship between business and society. These social contracts, moreover, derive from distinct cultural, economic and governance models. The rise of an indigenous version of CSR across Asia is therefore developing with both similarities and differences to that practiced in the rest of the world. Unique Asian realities are critical in shaping regional approaches to a sustainable and responsible business model, particularly in comparison to the United States and Europe, notably (Sharma, 2013; The Asia Business Council, 2008):

- Asia is more diverse—culturally, linguistically, and economically—than others regions of the world. First, it is a mistake to refer to one version of Asian CSR because it is defined differently across the region. Second, Asia taken as a whole, offers a fascinating tested where various approaches and models can be tried out.

- Asia is experiencing the most rapid economic growth of any of the world's regions. The promise and reality of rising living standards remain foremost in the minds of policymakers and businesses. This outlook contrasts sharply with Western perspectives, where the focus is more on maintain already high living standards.
- Asia, more so than other regions, includes a dynamic mix of developed and developing economies. Coupled with the rise of "South-South" trade, this mix positions Asia to influence other regions of the worlds on a range of issues.
- Asia's rising economic power coincides with increasing political power. China, India, and Russia are poised to assert ever more political influences in the coming decades, meaning that Asian perspectives on CSR may alter or argument global definitions of the concept.
- Asian businesses and policymakers are substantially less inclined than Western companies to rely on established international principles and standards on social and environmental questions. This inclination may reflect the fact that the standards are not universal, but were developed primarily by and for Western interests. It may also result from the desire to prioritize economic growth over other factors, and Asia's affinity for consensus-building, in contrast with the more legalistic approaches favored in the West.

These distinct features shape the way Asian companies and leaders define CSR, and also have impact on how "Made-in-Asia CSR" will influence global perspectives on sustainability.

Asian Models of Corporate Responsibility

CSR in Asia is evolving in different ways, each with its own priorities and mindsets. The original

CSR model emerged from Western multinational companies operating in Asia. Beginning in the early 1990s, American and the European companies began to apply a set of principles to the operations of their Asian suppliers and business partners. The rise of codes of conduct, focusing both on labor and environmental practices, can in retrospect be seen as an early effort to develop "soft law" principles for the globalizing economy (Sharma, 2013; The Asia Business Council, 2008). These efforts while often well-intentioned, in many cases reflected Western perceptions—and misperceptions—of Asia. Tied to sometimes controversial Western origins, this first conception of CSR has marked the development of three different approaches to CSR more firmly tethered to Asian thinking.

The first approach—based on the notion of community benefit—involves the practices of Asian companies doing business inside their own countries. While the subject is too diverse to be treated completely here, the basic premise is that companies can work together at the intersection of local conditions, community expectations, and at times, the inclinations of powerful business leaders who may be looking to establish—and demonstrate—a legacy of community benefit. The most interesting examples of this approach are the ones where companies create new business models for "blended" benefit, such as Industrial Credit and Investment Corporation of India (ICICI) Bank in India, which is aiming to bring new financing models to impoverished communities desperately in need of banking services. The second approach, is the arena of Asian-influenced CSR that has developed where Asian multinational companies shape—or choose not to—the communities in which they operate outside Asia. The third approach, is that, as the number of Asian companies operating in the United States and Europe grows, there is new opportunity for Asian business leaders to demonstrate their will to be good corporate citizens in these developed markets.

China Securities Regulatory Commission

The most notable development for the adoption of CSR in China at the turn of the century was the 2001 Code of Corporate Governance for Listed Companies issued by the China Securities Regulatory Commission and the State Economic and Trade Commission. This was the first ever recognition of the interest of “stakeholders”, a remarkably modern text but with little on implementation and enforcement (Sharma, 2013). Chapter 6 of the Code clearly extends CSR’s scope beyond labor issues to a broader range of activities, ranging from respect for legal rights of stakeholders to transparency in reporting on operations and financial situation of a company (China Securities Regulatory Commission and State Economic and Trade Commission, 2001).

The 2006 Company Law

When China first drafted the company law in the early 1990s, CSR was a little known concept. The 1994 Company Law explicitly addressed issues of labor rights and employee rights in Article 15 and 16 of the law, giving rise to China’s first ever stakeholder-friendly legal statute. The revised 2006 Company Law gives explicit recognition to CSR, by requiring companies to adhere to social and business ethics as well as fulfil social responsibilities.

Shenzhen Stock Exchange

In September 2006, the Social Responsibility Index (SSE) released a set of “Social Responsibility Guidelines for Listed Companies” (Unknown, N. Y.) that encourage listed companies to assume responsibility for social development, the environment and other natural resources, and commit to protecting the right and interests of shareholder, creditors, employees, customers, consumers, and others involved with their business. The SSE guidelines also encourage companies to regularly

evaluate and issue voluntary disclosures about their performance.

B

Emergence of Different Models

It is no more possible to define a single model of “Asian CSR” than it is to define a single Asian language. The region’s diversity of corporate practices rivals that of its natural environments. In India, philanthropy continues to loom larger in the CSR landscape. At the same time, civil society also plays a significant role in India, suggesting that until the now Western “stakeholder” model with the views of multiple players taken into account, could develop. Any such model, and indeed the overall approach to CSR in India, will also be defined by the tension between the country’s energetic commercial development and its cultural and spiritual values, which sometime run counter to a focus on simple material progress.

China’s rise has coincided with growing interest in CSR in Asia. For example, Hu Jintao’s drive for a “harmonious society” has focused increased government attention on the nation’s mounting environmental worries, as well as growing economic disparity (The Asia Business Council, 2008). Concerns about corporate governance, safety issues and frenzied stock speculation are bubbling under the surface, raising the possibility that pressure on the role of business in Chinese society could greatly increase. The insurance of a directive from the State-owned Assets and Administration Commission to state-owned enterprises to adopt CSR is but the latest sign of interest from the central government in Beijing.

In Northeast Asia, while Japan and Korea have experienced historical conflict, they share relative prosperity, as well as concerns about the economic and political impact of their Chinese neighbor. Japanese and Korean multinationals are showing increased interest in the global CSR dialogue. With fellow Korean Ban Ki-moon as Secretary-General of the UN, Korean business may be more inclined to align its energy-saving practices with those of the UN Global Compact.

Across Southeast Asia, smaller economies from Vietnam to Cambodia to Indonesia focus mainly on economic development and their role as suppliers to global manufacturers. Apart from Indonesia's effort to legislate CSR, these nations are not yet shaping distinct approaches to CSR. Hence, the trading hubs of Hong Kong and Singapore have increasingly active CSR communities. These two cities might well become to Asia what London has become in Europe: centers of debate and innovations that can inform and invigorate practices around the region.

FUTURE RESEARCH DIRECTIONS

What happens in Asia matters, because this is not only because so much of the world's economic energy comes from the region, but also because the global challenges that CSR is designed to address are more vividly on display in Asia than elsewhere. Any look at global mega-trends will find countless examples of CSR at work today from Tokyo to Karachi. Asia leads in the number of mega-cities, which bring both economic opportunity and environmental nightmares. Asian is also home to both demographic "youthquakes" with explosions of growth in the younger population such as in Vietnam, and fast-aging populations such as those in China, Japan, and South Korea. Asia has massive migration both within and across national borders. Many Asian societies, such as Korea, are champion early adopters of information technology. But Asia is experiencing rapidly changing social contracts, with questions about governance gaps and power shifts across the region.

The evolution of CSR in the West over four distinct periods offers some lessons in how Asian businesses might consider incorporating the concept into their business strategies. The first phase, in the mid-1990s, companies' actions were characterized by reaction. In this phase, businesses responded, often with defensiveness, as new issues landed on their agendas. The second phase, companies began to look to innovation, focusing

on the reaction of best practices. All too often, however, such efforts developed only as demonstration projects that could not be scaled up. The third phase, begun earlier this decade, saw a welcome focus on integration. With this approach, companies began to integrate social and environmental questions into their core activities. More recently, businesses have begun to look at how CSR can generate value creation. This latest idea means the development of new markets, products and services that create top-line benefit, and build sustainability into the business, rather than just as a coat of "sustainability varnish" layered on top of an existing business model (Sharma, 2013; The Asia Business Council, 2008).

CONCLUSION

Compliance to the existing legislative and regulatory framework should be the mantra for CSR in Asia for the current generation of corporation of corporate entities. State capacity to enforce compliance by industry is very often constrained by pervasive corruption and the limited resources of the developing economy governments. In the individual country narrative it is amply evident that in many countries the poor state of labor rights or environmental degradation is not a result of inadequate regulation, but the weak enforcement of national and local laws (Sharma, 2013). Enforcement is the basic first step for governments to create a compliance culture and an environment conducive to industry taking on responsibility citizenship beyond compliance.

With CSR, business is being required to replace that regulatory approach or face a backlash from society. It may behoove the corporate sector in Asia to work on building the regulatory and enforcement capacity of governments so that business is not expected to play this governing role in the future. CSR can in fact be business' willingness to contribute to the governance deficit today, not by usurping that role, but building public institutional capacity to level the playing field

not only across business but across stakeholders. Hence, it may well be the SME that will define the CSR trajectory in the years to come. Closer to the community it operates in, the SME sector as a collective is the largest employer in most economies. In the 30 countries that comprise the Organization for Economic Co-Operation and Development (OECD), SMEs represent over 95% of enterprises in most countries and generate over half of private sector employment

KEY TERMS AND DEFINITIONS

Corporate Reputation: It is the process of creating influencer strategies that deepen understanding, build trust and mitigate risk in complex, ever-changing environments.

Corporate Social Responsibility (CSR): It is a concept whereby companies integrate social,

environmental, and health concerns in their business strategy (policy) and operations and in their interactions with stakeholders on a voluntary basis.

Government Linked Corporations (GLCs):

A term that is related to Asian businesses where companies in which some of the shares are owned by the government.

Local Private Companies (Privately Held Company or Close Corporation): It is a business company owned either by non-governmental organizations or by a relatively small number of shareholders or company members which does not offer or trade its company stock (shares) to the general public on the stock market exchanges,

but rather the company's stock is offered, owned and traded or exchanged privately.

Multinational Corporation [(MNCs) or Multinational Enterprise]: It is an organization, that owns or controls productions of goods or services in one or more countries other than the home country.

Stakeholders: Are those individuals, organizations who 'hold' a 'stake' in your organization's interests.

Stakeholder Relations: It is about improving your professional relationships - or lack of them - with governments, regulators, membership, industry, media or communities.

B

Digital Transformation Journeys in a Digitized Reality

Jurgen Janssens
QSpin, Belgium

INTRODUCTION

Big Data and Digital Transformation are hot topics since several years.

Big Data are large volumes of data from one or more sources, analyzed through innovative information processing to develop insights, resulting in better business decisions and process adaptation¹. Estimates of Turner, Reinsel and Gantz (2014) expect human and machine data to increase to 40ZB by 2020.

Digital Transformation implies often Big Data powered changes (Mayhem, Saleh, & Williams, 2016). Whereas concrete outcomes of the latter are booming, Digital Transformation is still seen as a faraway future. Nowadays, however, companies and organizations should not ask themselves anymore how to prepare for the upcoming Digitization, but how to adapt to and in today's Digitized/Digitizing World.

To get there, they need to understand how to evolve by embracing new technological potential and by looking through the blurring frontiers between offline and online reality. They have to take changing habits and continuously transforming customer segments into account. They have to look beyond the mere 'product' and 'selling to customers' angle (Richter, & Wee, 2016). To keep their value, companies, organizations and even governments need to understand that mental mobility of people and their data-stimulated ecosystem have turned people's need for products in a need for shaped services.

This has a significant impact on the strategic vision. Typically, this requires a new way of working adapted to the redefined borders between

reactivity and proactivity, and to the attention for real-time service and contextual adaptation. An organic compromise has to be found that answers the need for creative freedom and the need for an environment where management and development of human capabilities are possible in a structured way.

This article will shed light on core components for Digital Transformation. Concrete methodologies will also be analyzed that can guide the process of reviewing company fundamentals in the Digital Reality.

It will be explained that human means and data power need to be developed to develop a company's digitally quantified intuition² and to get most out of the customer journey.

Altogether, this article will illustrate that the success of Digital Transformation goes through integrating technological possibilities and dynamic customer journeys in the corporate DNA. It will require a new internal perspectives on projects, and create a new dynamic that, in the end, will allow people, companies and public and private organizations to be in the driving seat of this Fourth Industrial Revolution.

BACKGROUND

Reflections about Digitization and Digital Transformation exist since several years, also on intergovernmental level³. With technology developments in various fields amplifying one another, this will continue. It will lay the foundation for a revolution more all-encompassing than anything seen so far (Schwab, & Samans, 2016).

DOI: 10.4018/978-1-5225-2255-3.ch059

There are several risks if the dynamic is not engineered and managed correctly.

First of all, companies need to be aware that Digital is not an add-on, but the very essence of the transformation journey to remain in the game (Henke, Libarikian, & Wiseman, 2016). It involves a change in leadership, new business models, and an increased use of technology to improve the customer experience. It is only by integrating this Digital backbone that Digital strategies can have a lasting effect. Digital is one of the main reasons half of the companies on the Fortune 500 have disappeared since 2000 (Nanterme, 2016). Failing to understand its functioning can thus lead to companies losing their relevancy.

Traditionally, Digital Transformation is covered from separate angles.

Certain sources analyze the impact of technology on job markets and human employability (Van Driessche, 2014). Others focus more on specific pieces of the corporate landscape – ranging from the need to extend the CxO suite with a Digital Officer, to the development of a new way of thinking, or the analysis of managerial choices to be made for techn(ological) transition.

Solely focusing on subsections risks to lead to an incomplete integration of the Digital dynamic. At best, the initiative will be an intermediary step. At worst, it will create a negative spiral that funnels means, time and potential - a risk further reinforced by the speed at which Digital is unfolding.

On the methodological level, a similar tendency can be observed. Agile frameworks like scrum⁴ or Kanban⁵ ensure guidance of essential aspects for agile product delivery (Galen, 2013). It is however less common to have agile covered for more profound transformations like those observed in the Digital Age.

The author wants to bring the components of the Digital journey together. Shaping their complementarity should open the possibilities of a new way of thinking about customers, organizations and projects, about shaping service and product delivery, about interacting with the ecosystem - and about creating value.

SOLUTIONS AND RECOMMENDATIONS

Changing Ecosystems, Dynamic Needs

Companies are continuously challenged to raise the bar, or to reinvent themselves. Digital Transformation is seen as one of the means to get there. This transformation is already well underway. Early 2016, the World Economic Forum in Davos called it the Fourth Industrial Revolution (Schwab & Samans, 2016):

Today, we are at the beginning of a Fourth Industrial Revolution. Developments in genetics, artificial intelligence, robotics, nanotechnology, 3D printing and biotechnology, to name just a few, are all building on and amplifying one another. (...) While the impending change holds great promise, the patterns of consumption, production and employment created by it also pose major challenges requiring proactive adaptation by corporations, governments and individuals.

Besides the semantical discussion to call it Digital Transformation or Fourth Industrial Revolution, facts are there that illustrate the vastness of this evolution (Carter, 2015). The world's largest taxi firm, Uber, owns no cars. The world's most popular media company, Facebook, creates barely content. The world's largest accommodation provider, Airbnb, owns no property. So, vast changes are already ongoing.

In fact, private and public actors have already interwoven Digital in everyone's day-to-day. The British government, for instance, is coached by scientific experts of the Behavioural Insights Team⁶, amongst others to improve processes like the reduction of late paid taxes (Van Leemputten, 2016).

This is also true for private companies. Thanks to PlayStation, Sony's revenue is growing for services like the selling of data to game producers. These data allow third parties to understand

the way players navigate through games, and increase the user experience. As for car insurance companies and marketers use driving habits and machine data from connected cars to adjust risk-pricing models and fee structures.

One of the biggest changes of Digital is thus the transition from a product and competition based economy to a service and customer journey focused reality. Companies have to manage and make sense of data to provide services. This is a major change for product focused companies. The opportunity, from a service perspective, is to rethink the way to satisfy a customer's need through a service, especially as many services that can be created through the Digital World were not there before (Edelman, 2016).

The Digital Age is thus very present. Modern society is in the midst of it. At its core, it is fundamentally changing the value proposition to and from the customer. The question is thus not anymore how to prepare for it, but how to live and work in it.

Anticipation and Adaptability

Before analyzing strategy development or actionable translations, it is important to agree on what Digital really is. For some, it is about adding high tech niches to the portfolio. Others see it as collecting zealous amounts of data, being in constant communication with customers, or completely reshaping the company.

In practice, it is a dynamic sequencing of each of the above. It is a new way of thinking about service and product delivery, about organizing a company, about understanding and interacting with the larger ecosystem - and about creating value.

Digital Transformation can be defined as a process in which an organization is shifted to new ways of working and thinking with digital and social technologies. It involves a change in leadership, a different thinking, the encouragement of innovation and new business models, and an increased use of technology to improve

the experience of an organization's internal and external customers (Terrar, 2015).

Digital Transformation is thus not really about technology itself, but about how companies integrate it to transform their businesses and shape the way of working.

With data collection happening more through apps, for example, people can be seen as customers that use the apps' services. But as data generated by people are increasingly managed by the people themselves, consumers are, for instance in healthcare, turning into suppliers. This leads to the obligation to rethink products or develop new services (De Brouwer, 2015). Similarly, the supply chain is needed to efficiently deliver the correct product. At the same time, process KPIs and user data can be used to build insights about customers, and continuously fuel improvement for production, marketing or transportation.

Embarking on Digital is thus about shaping a dynamical way of working. With a clear strategy, skilled people and powerful data, digitally activated companies should get a fine-grained sense of the interactive relations between customers and their ecosystem, take proactive decisions based and, ultimately, adapt their business models to shape people's journey-focused experience.

Strategic Vision: Models and Methodologies

Organizations are facing a major challenge to reinvent themselves. To help them, professionals have developed tools that make this Digital process more tangible and the outcome more actionable.

In the Digital Transformation process, a clear baseline reference can be built based on the Digital Quotient. This metric for the Digital Maturity of a company has been developed by consultancy company McKinsey, based on an evaluation of 18 practices related to digital strategy, culture and capabilities, in 150 companies around the world (Catlin, Scanlan, & Wilmott, 2015).

The Digital Quotient is driven by four main components.

- **Strategic Commitment:** Companies must not go for digital as an add-on of their core business, but by wholeheartedly committing to a clear strategy.
- **Development of Digital Capabilities:** Digital success depends on the ability to invest in the relevant capabilities. They need to be sized for and aligned with the strategy.
- **Adaptive Culture:** In complement of technical capabilities such as Big Data analytics and the like, a strong and adaptive culture helps to compensate for a lack of them.
- **Internal Coherence:** Organizations need to align their internal structure, talent management and key performance indicators with the chosen Digital strategy.

Companies that desire to launch the transition to becoming Digital-ready can shape their roadmap by making choices with regards to the components of the Digital Quotient. This vision is the foundation for future actions and the management with a clear sense of direction.

Various frameworks are available to make the strategy actionable. A holistic approach to structure it from conception to realization has been developed by Jo Caudron and Dado Van Peteghem (2014). The 'Digital Transformation Modeling' methodology aims at clarifying the potential impact of Digital on an organization's activities and builds an action plan based on these insights.

In essence, the process consists of five steps:

Step 1 - Creating Insights:

- Understanding that a company can be impacted by and needs to prepare for Digital Transformation. This is traditionally initiated by one of the company's stakeholders.

Step 2 - Assessing Potential Impacts:

- Assessing impacts is done by evaluating the readiness of the company with regards to seven Drivers for Impact, and their respective constituents.

- Each of the Drivers for Impact is represented by an analogy: The Glasshouse, The Package, The Frog, The Gatekeeper, The Traveler, The Participant, The Cyborg⁷.
- The 'Cyborg', for instance, represents the impact driven by a series of technological evolutions, like the growing automation, the possibilities coming with real time data power, or additional potential offered by the Internet of Things.
- The 'Frog' materializes the fact that evolution does not have to be gradual anymore, but can be driven by shortcuts. The speed of insights, for example, can allow much faster reactions. Virtualization fits in this logic as it allows companies to jump over competitors more easily.
- Figures 1 and 2 illustrate the evaluation of the Drivers of Impact for an existing Glass Manufacturing company, and an existing Consultancy company. The evaluation has been done companywide. The former has more medium risks (amber). The latter has more risk factors under control (more black/green, less amber), but more risks with high impact (red).

Step 3 - Developing Scenarios:

- By developing scenarios, the reality resulting from the combination of two risk factors is evaluated. A risk factor is one of the main Drivers of Impact, or one of its major constituents.
- This leads to four possible scenarios: risk factor 1 and risk factor 2 have a high impact, 1 high and 2 low, 1 low and 2 high, 1 low and 2 low. In practice, this results only in three useable scenarios, as the last one offers little added value compared to the existing situation.
- Each combination represents a high risk environment that could become

Figure 1. Evaluation of the drivers of impact for an existing glass manufacturing company

The GlassHouse	The Package	The Frog	The GateKeeper	The Traveller	The Participant	The Cyborg
Transparency	Monolithic vs Atomic	Bypassing	New gatekeepers	Place	Community	Internet of Things
Accountability	APPlification	Virtualization	Recommendations	Utility	Gamification	Wearables
Proximity	Long Tail	Fragmentation of Touchpoints	"Good is good enough"	Empowered Self	Collaboration	Quantified Self
Responsiveness	Personalised		Ambassadorship	Instant Gratification	The power of the crowd	Robotics
Bi-directional	Experience			New way of working		Data
Humanization	Speed			Contextual Awareness		Monitoring
Authenticity	Value for Money					
	(Self-) Service					
	Scalability					
Team(s)/Departement(s)/Division(s) concerned by the assesment: All Glass Divisions						
White: has 0 impact in a digital context.	Green: has an impact (in a digital context), plan is defined and actions in motion.	Amber: has an impact (in a digital context), plan is existing but nothing in motion yet.	Red: has an impact (in a digital context), but no plan or action put on paper.			

reality when both conditions are combined (or an existing risk reality for which a solution needs to be found).

- For each scenario a headline should be provided (Figures 3 and 4), as well as a detailed report of how to tackle the risks.

Step 4 - Building Business Case(s):

- Based on the scenarios, actions need to be defined to avoid such a scenario to happen (or to turn the risks in opportunities). This will result in the building of one or more Business Cases.
- Once the Business Case is approved, the 'traditional' transformation life-cycle starts, at the organizational level, process level, IT level, or combined at multiple levels.

Step 5 - Staying Alert Through Trend Watching:

- To ensure a lasting effect of the awakening created by the start of the Digital journey, it is important to stay alert through structural trend watching and periodic workshops.

Empowering Digital People

The Business Case might reveal gaps in terms of technical power or human capabilities. Whereas the data side can be managed through technological gear-up and anticipative sizing, human gaps have to be tackled by developing transversal capabilities. This means focusing on customer value, data experimentation, ecosystem collaboration, Digital platforms, and maturity (Viaene, 2014).

To support the transformation, pockets of catalytic potential have to be foreseen (Janssens, 2016). The ideal people have a healthy level of 'functional craziness' and are seasoned to think beyond the traditional silver lining. At the same time, companies need to be aware that skills disruption is an urgent concern in the Digital Age (World Economic Forum, 2016). Consequently, companies need to look for people for their proverbial Digital SWAT Team, and, increasingly, for people with a high adaptability.

To ensure compatibility, organizations need, firstly, to create a stimulating environment. Methods to do so are available in spades, going from Google Ventures' proven techniques (Brillantes,

Figure 2. Evaluation of the drivers of impact for an existing consultancy company

The GlassHouse	The Package	The Frog	The GateKeeper	The Traveler	The Participant	The Cyborg
Transparency	Monolithic vs Atomic	Bypassing	New gatekeepers	Place	Community	Internet of Things
Accountability	APPification	Virtualization	Recommendations	Utility	Gamification	Wearables
Proximity	Long Tail	Fragmentation of Touchpoints	"Good is good enough"	Empowered Self	Collaboration	Quantified Self
Responsiveness	Personalised		Ambassadorship	Instant Gratification	The power of the crowd	Robotics
Bi-directional	Experience			New way of working		Data
Humanization	Speed			Contextual Awareness		Monitoring
Authenticity	Value for Money					
	(Self-) Service					
	Scalability					
Team(s)/Departement(s)/Division(s) concerned by the assesment: All Consultancy Practices						
White: has 0 impact in a digital context.	Green: has an impact (in a digital context), plan is defined and actions in motion.	Amber: has an impact (in a digital context), plan is existing but nothing in motion yet.	Red: has an impact (in a digital context), but no plan or action put on paper.			

Figure 3. Example of a scenario evaluation for a glass manufacturing company, based on the risks coming from a new way of working, and major cyborg elements

2015; Knapp, Zeratsky, & Kowitz, 2016) to more anarchical approaches (Bushnell & Stone, 2013). As such, it comes down to creating a culture where thinking beyond the traditional frames of reference is stimulated.

In complement, it can be fruitful to see if hidden gems were discarded due to traditional analysis. At Atari, this was part of the corporate DNA. They would periodically list the worst ideas of the past period, and brainstorm to turn them into

Figure 4. Example of a scenario evaluation for a consultancy company, based on the risks coming from the frog, and major cyborg elements

good ones. At worst, it offered precious lessons. At best, it resulted in a huge success (Bushnell & Stone, 2013). Google is following a comparable approach to turn insights of past (failed) projects into ingredients for new ones.

Secondly, companies and organizations need to nurture their people for and with Digital.

It is important to retain high performers as they have a beneficial influence on results and potentially on other colleagues. Similarly, by doing predictive HR management, employee expectations can be anticipated and employees can be identified that need mentoring. Google's People & Innovation Lab, for instance, uses data-based people management to anticipate employee aspirations and to monitor impacts of individual relations on team performance. Even if not every company has the same data power, proactive management benefits the internal dynamic and the outcome on bottom line Digital productivity.

Thirdly, the different levels of management need to learn to talk Digital. Leaders need to be able to exchange with their experts, ask them

questions and, at least, understand the essence of their answer. This will reinforce people's faith and contribute in staying alert for continuous reinvention and adaptability.

Overall, having the appropriate human capital on board is thus one of the cornerstones to manage digitally. This implies creating an appropriate environment and culture for these people, nurturing them, and managing them with a solid understanding of what Digital means for them.

Dynamic Feedback and Agile Projects

The biggest challenge for the execution of the Digital Strategy is the structural integration of the fundamental paradigm shift. Pre-Digital organizations focused on market share and people got managed accordingly. In the Digital Economy, companies need to be designed for reactivity, flexibility and agility. An integrated operational backbone is needed that embraces a continuously

Figure 5. A fair share of the nimble way of organizing the work for reactivity and agility is coming from agile software development. Collaboration with tradition waterfall approaches might be needed.

evolving service backbone, and a clearly articulated, but dynamic business strategy (Ross, 2016).

A fair share of this nimble way of working is initially coming from agile software development, focusing on rapid prototyping and getting releases out smoothly. This philosophy is now also influencing the development of business deliverables. For details on agile approaches, the author refers to dedicated literature⁸. But some important attention points should be taken into account.

Firstly, it should be noted that the structural fluidity associated with agile methodologies requires maturity and discipline. Scope control and regular iterations are part of the Agile principles. Success comes thus not from the speed of idea generation alone. Rather, it is the unconditional availability of decision takers towards rapid feedback that makes the difference.

Secondly, the feedback and follow-up loops need to be managed with conviction. No matter if they are scrum or Kanban inspired, reviews need to aim at real quality. Indirectly, this implies that baselines and reference points remain important to fuel further improvements.

Thirdly, to fit in the larger corporate ecosystem, agile perimeters might have to blend with more traditional ones (see Figure 5). To make such a hybrid context function, compromises are needed. In case agile subsets are, for instance, inserted in a larger waterfall based environment⁹, they will have to work with a smaller degree of autonomy

and with a different perspective on due dates. Waterfall entities, on the other hand, will have to adapt to a more flexible way of working.

Similarly, a critical mind is needed with regards to theories advocating radically simplified approaches, like replacing strict controls by minimal or no budgets, or intuitive prioritization (Laloux, 2014). Digital companies still need guidance. The ‘simplification’ should therefore be limited to a leaner way of working, rather than going for a full deconstruction of supporting frameworks.

Most importantly, the overarching focus on agility should not become a goal on itself. In a reality where decisions have to be made quickly based on continuously evolving insights, companies should be able to develop their quantified intuition, and take decisions that make a difference. The aim of agility is therefore to support the overall goal: providing appropriate solutions to customer needs and preferences.

FUTURE RESEARCH DIRECTIONS

Algorithms power businesses like Amazon and Netflix. Health related apps are changing the medical world. And research about industries like hotels and retail indicate that benefits of skilled sales force may be diminishing in an increasingly data-driven world (Philips & van Ryzin, 2016).

Digital Transformation is thus providing society with substantial opportunities, as well as with challenges in the dynamic relation between agile organizations, rapid decision taking and the role of Big Data powered artificial intelligence.

This raises the question whether machines or people should take decisions to provide the necessary value in the Digital Age. At the same time, it indicates that specialists and managers need to be able to sharpen their Digital Capabilities and elevate their quantified intuition to a higher level, in order to remain in control of their organization. To do so, several elements could be further explored.

From the methodological point of view, the project management toolbox has to be further enriched with specific best practices. They will have to dedicate specific attention to the permeable delimitation between product delivery and service delivery. Likewise, cook books for hybrid contexts would be valuable. This will not dilute the role of project management frameworks and dynamic organizational management, but will improve compatibility with the Digital Reality.

Likewise, it will be valuable to analyze if best practices could be identified for specific sub-sectors. Also, attention to the public sphere would be valuable. By bringing public and private practices on par, it is imaginable to activate the potential of the public-private force field in domains like education, health or city management. In turn, this could benefit corporate and individual ecosystems.

Obviously, best practices will require continuous improvement. But the author believes that recurring efforts will be largely compensated by advantages in quality and outcome.

CONCLUSION

Managing the Digital Transformation is not a high-tech option for a faraway future. It is about how public and private organizations integrate technology to transform their businesses. It involves a change in leadership, a different thinking, new business models, and increased use of technol-

ogy to improve the customer experience. It is by integrating this backbone that Digital strategies can have a durable impact.

To get there, a series of key points have been addressed.

Firstly, it has been explained that a thorough understanding of the new reality is essential. The Fourth Industrial Revolution redefines borders between reactivity and proactivity, and creates the need for real-time service and contextual adaptation. It requires a dynamic silver lining, compatible with interactive work clusters and a hybrid organization.

It has been explained that this understanding needs to be integrated a strategy to profoundly revisit the company, encompassing the internal way of working, as well as the customer value proposition, the articulation of the product/service portfolio and the related follow-up dynamics.

Secondly, practical approaches have been analyzed that can guide this process. With the Digital Quotient, organizations have a baseline to put findings into perspective. Similarly, by embracing the Digital Transformation Modeling framework, a solid methodology is available to clarify the potential impact of Digital, create future scenarios for the Digital Age, and build an insight-based action plan.

Thirdly, it has been highlighted that putting a strategy into motion for Digital success implies an appropriate organizational way of working and managing.

Lastly, it has been explained that the Digital way of working needs to be inspired by an agile philosophy. When doing so, organizations and managers are namely better prepared to develop their quantified intuition, and take relevant decisions for the company and its customers.

Overall, Digital Transformation projects are thus part of a major change journey. A journey that shapes the present to be ready for an already ongoing future - and that will continue to transform at high speed. It is a new way of thinking about the interaction with customers, about shaping service and product delivery, about organizing an organization - and about creating value.

KEY TERMS AND DEFINITIONS

Agile: Project management methodology in which the development is characterized by the breakdown of tasks into short periods, with frequent reassessment of work and plans. Used in software related projects and digital transformation activities.

Big Data: Large volumes of structured, semi-structured and unstructured data from one or more sources, created and analyzed through innovative forms of information processing to develop insights on patterns, especially on human behaviour and corporate interactions, resulting in better decisions, strategic business decisions, and process adaptation. Characterized by high volume, high velocity and/or high variety.

Digital Quotient: Metric of the digital maturity of a company, based on the evaluation of a series of practices related to digital strategy, capabilities, and culture.

Digital Transformation: Process in which human and corporate society is shifted to new ways of working and thinking with digital and social technologies. Involves a change in leadership, a different mindset, the encouragement of innovation and new business models, and an increased use of technology to improve the experience of internal and external customers.

Digitization: Process in which an object, image, sound, document or signal are represented by a series of numbers that describe a discrete set of its points. Often used as synonym for the larger process of Digital Transformation.

Fourth Industrial Revolution: Industrial revolution driven by systems involving entirely new capabilities for people and machines. Represents new ways to embed technology in society, and induces new ways of working and thinking for human and corporate matters. Used as synonym for Digital Transformation.

Quantified Intuition: Non-technical capability that helps in making impactful decisions at a fast rate, despite a high level of uncertainty and an important inflow of interconnected data.

Scrum: Iterative and incremental product development framework used in agile projects.

Waterfall Project Methodology: Sequential project management methodology, in which project progress is regarded as a downwards process. Originally described as consisting of phases for Requirement Specifications, Design, Construction, Integration, Testing, Installation

and Maintenance, variations exist on the naming and number of phases.

A Framework for Exploring IT–Led Change in Morphing Organizations

Sharon A. Cox

Birmingham City University, UK

INTRODUCTION

Organizations must continually change to survive, adapting to changes in their social, economic and trading environments, responding to the changing needs of customers and reacting to competition. Organizational transformation refers to changes in the way in which an organization operates. Morphing organization is a term used to reflect organizational transformation, recognizing that as an organization changes its outer face displayed to the world, internal structures and processes within the organization must change to facilitate and support the external interface. A morphing organization has an identity that is determined by the organization's relationship with its environment, its internal components and the social practices in which the participants in the organization interact. As the external face of the organization changes and internal components are adjusted, core structures and values need to be retained in order to maintain the organization's unique identity (Cox, 2014).

Developments in information technology (IT) have been and continue to be, a major driver of organizational transformation. IT has changed the structure and face of organizations in most industries and it is recognized that introducing and changing technology in an organization is not merely an IT issue (Jackson & Harris, 2003). For example, the impact of ebusiness transformation of organizations is well documented. Technology has changed the way in which customers and suppliers interact with the outer face of the organization, and transformed the back office pro-

cesses needed to support the external face of the front office activities. The wider implications of changing IT systems in organizations as an enabler of organizational change need to be considered.

The contribution of this chapter is the presentation of an organization architecture to explore the impact of IT-led change in morphing organizations. The framework of the organization architecture offers a coherent structure in which to consider organizational transformation in response to IT-led change, to structure analysis and evaluation of the aspects of an organization that may be affected by proposed changes to IT systems in an organization. The framework may also be used retrospectively to analyse how changes in IT have led to organizational transformation. The organizational architecture builds on the McKinsey 7-S framework (Peters & Waterman Jr., 2004) and considers the impact of IT changes to both formal elements of the organization such as organizational processes and informal elements such as social values. The application of the organization architecture is illustrated through case study examples from UK organizations.

The following section discusses organization identity. A business model is discussed showing the relationship between an organization and its trading environment focusing on the external face of the organization. The internal structures that support the external organization identity are then discussed. An organization architecture is presented as a model to explore the changes in the organization needed to accommodate IT and how an organization may be affected by changes to IT. The chapter concludes by considering the

challenges of the third wave of IT-led change, predicted by Porter & Heppelmann (2014), to organizational identity.

BACKGROUND

Identity is the most fundamental concept of humanity and is the essence of an organization, which emerges through communication and interaction between members of the organization (Koskinen, 2015). The act of identifying an organization establishes a conceptual boundary around a group of people, resources and activities. Defining an organization separates the organization linguistically from other things (Koskinen, 2015), creating an entity with a unique identity. The relationships between the organization, its customers, suppliers, competitors and trading partners can then be explored.

Whetten (2006) uses the phrase ‘organizational identity claims’ or ‘referents’ in relation to the attributes of an organization that form its identity. These are enduring attributes that reflect the core values of an organization and are tested by considering the question of whether the organization would be the same organization without a specific attribute.

In the same way that the view an individual holds about themselves may differ from the way that others see them, there is the identity of how others see the organization and how those inside the organization perceive the organization. Balmer (2008) uses the term *corporate identity* to reflect an external view of how the organization is perceived by those outside the organization, such as customers and the term *organizational identity* to reflect the internal view of how the organization is perceived by those within it. Koskinen (2015) uses similar terms to represent these two views and adds a third form of identity:

- *Company identity* is how the organization presents itself to its environment.

- *Reflective identity* is how the organization sees itself internally.
- *Substantive identity* is the mechanism that keep the different parts of the organization focused as a single unit.

B

An organization’s identity is created by the decisions and practices in an organization, which in turn influence the identity. Koskinen (2015) describes identity as the hidden face of strategy. Accurate identification of organizations is essential (Whetten, 2006) and attention to the organizational identity is particularly needed during periods of change (Albert & Whetten, 1985). The following sections discuss two models: the business model and organization architecture that reflect the *company identity* and internal *substantive identity* respectively.

Business Model

Organizations operate within an external trading context that is represented in a business model. All organizations have a business model (Andersén *et al.*, 2015). A business model is a way of doing business focusing on the organization’s competencies (DaSilva & Trkman, 2014), reflecting the relationship between control and value in the organization (Ballon, 2007). Business models identify key aspects of an organization that determine how the organization positions itself in its market(s) and industry(ies) in order to create, maintain and reflect its unique identity.

Osterwalder *et al.*, (2005) identified nine elements in a business model:

1. Value proposition (products and services offered by the organization).
2. Target customer segments.
3. Distribution channels (used to reach customers).
4. Relationship (links between organization and customer segments).
5. Value configuration (arrangements of activities and resources)

6. Core competency (of organization exploited in business model).
7. Partner network (co-operative agreements with external parties).
8. Cost structure.
9. Revenue model (how it makes money).

Most of the elements identified by Osterwalder *et al.*, (2005) focus on the external relationships of the organization. Koskinen (2015) suggests that although business models represent the external relationships of an organization, business models are not sufficient to understand the history and evolution of the organization, which contribute to the organization's identity. Although a business model may include some referents of company identity, it is insufficient for examining the organization's substantive identity and how the internal context will be affected organizational transformation.

Figure 1 shows a generic business model (Cox, 2014) comprising three sets, the organization,

market and business environment situated within the wider business climate.

The business model provides the context for the organization's identity and identifies the external stakeholders, which may provide opportunities and constraints for the organization achieving its vision. The organization architecture forms the context for substantive identity within the organization set of the business model and provides the contextual framework for activity in the organization; changes to the organization architecture trigger and facilitate organizational transformation. Organizational change may be initiated in response to external changes in the market, business environment or business climate, for example, changing customer expectations, changing industry standards or legislative requirements. Organizational change may also be internally initiated, for example, by new management.

The performance of an organization and the outcome of organizational change emerge from the interaction between the organization's struc-

Figure 1. Generic business model
Source: Cox, 2014

tures, individuals within the organization and the organizational strategies, which form the context for technology use (Yeo & Marquardt, 2015) in the organization architecture. Much of the research about organizational design focuses on organizational structures (Sherif *et al.*, 2013). For example, Ethiraj & Levinthal (2004) consider organizational design based on two choices: the number of departments and the assignment of functions to departments. Organizations need to have sufficient flexibility to enable them to respond to the demands and opportunities of innovations in IT, balanced with stability to maintain their unique identity. Sherif *et al.*, (2013) describe an ambidextrous structure as one that allows organizations to move between organic and mechanic organizational structures depending on market conditions.

Organization Architecture

Business models focus externally on the relationship between the organization and its trading environment, in contrast the organization architecture focuses internally on the structures and components that maintain the external organization identity.

The organizational architecture is different to the organizational structure. Sherif *et al.*, (2013) describe an organization architecture as a high level map of the organization that includes people, processes and technology. The formal and informal organization structure form part of the organization architecture. The organization structure groups resources, provides a boundary for activities to be controlled, and determines the flow of information, authority and decision-making responsibility through the organization. An organizational architecture creates behavioural space, which provides opportunities and constraints for organizational activities. The architecture provides a boundary for activity, shaping the organization. Saucer & Willcocks (2004) emphasize that defining the organizational architecture is not a one-off task (like designing a building); it is a continuous process

of adjustment to meet the changing needs of the business environment.

Sherif *et al.*, (2013) suggest that the organization architecture includes three architectures:

- Business architecture: organizational capabilities (services, processes and information) translating the strategic objectives into processes and competences.
- Infrastructure architecture: technical capabilities (hardware and telecommunications) supporting business processes
- Application architecture: governance capabilities monitoring and controlling activities.

Waterman Jr. *et al.*, (1980) proposed that organizational effectiveness emerges from the dynamic interactions between the organization's structure, strategy, systems, style (of management and culture), skills, staff resource (including morale, attitude, behaviour, training and appraisal) and subordinate goals (later renamed shared values (Peters & Waterman Jr., 2004) representing the values underlying the mission of the organization). This became known as the McKinsey 7-S framework©. Each area of the 7-S framework is connected to the others (Kaplan, 2005), demonstrating that change in any of the seven areas will trigger change in the other areas.

Organization Change

Changes in an organization can range from minor changes to improve efficiency through to the complete destruction and redesign of structures and systems (Senior & Swailes, 2010). Ethiraj & Levinthal (2004) differentiate between first-order change (incremental change within the existing organizational structure) and second-order change to the underlying structures to align with environmental demands. Dunphy & Stace (1993) identify four types of change within this broad spectrum of minor modification to major redesign. Each type of change differs in terms of the scope and

scale of the change in the organization. First, fine tuning involves minor adjustments, which may be restricted to one department and may be internally triggered, to improve organizational alignment of strategy, structure, people and processes. Second, increment adjustment may affect one or more departments with the aim of improving the operation of the organization by modifying strategies, structures and management processes in response to changes in the external environment. Third, modular transformation relates to the restructuring of one or more departments and changing the co-ordination of activities between departments. Fourth, corporate transformation involves revolutionary change of the strategy, structures and systems in the organization, requiring wide scale redesign of the organization, challenging organization identity. Organizational change is often triggered by IT.

IT-LED CHANGE

Organizations must adopt and embed information technology into their social practices in order to meet the changing demands and expectations of their trading environment. IT can lead to structural changes in organizations (Goksen *et al.*, 2015) as technology can be used to change the flow of information, control and decision-making. Organizational participants respond to IT in different ways, leading to change in the organization architecture to accommodate the technology and posing threats to the organization's identity.

IT can constrain or enable change in organizations (Yeo & Marquardt, 2015). IT has been deliberately used as a vehicle to initiate cultural change in organizations, for example, e-government has been introduced with the aim of transforming public sector services (Yeo & Ajam, 2010). However, the introduction of IT or changes to IT, can lead to both intentional and unintentional consequences in the organization (Yeo & Marquardt, 2015).

The design of technological systems embodies business rules that constrain actions in an organization, though constraints can be resisted and lead to unintentional consequences. For example, Boudreau & Robey (2005) discuss a case where a feature of the system was that it would automatically log-off users who did not interact with the system for a defined period in order to increase security. Users did not like the lack of freedom to leave the system unattended, partly because of the length of time taken to log-in. Users therefore devised ways to "beat the system" such as by asking others to simulate actions for them (Boudreau & Robey, 2005). Although the intention was for the system feature to increase security, an unintended consequence of the system was that it decreased security as staff developed ways of working around the system controls.

Figure 2 presents a 2x2 grid to reflect the positive and negative impacts of IT on organizations. The grid forms four sectors:

Sector A: As in the log-in example (Bordreau & Robey, 2005), technology can restrict actions, which may result in unintended consequences as staff seek ways to work around the restrictions.

Sector B: In contrast, positive side effects can emerge from technology through facilitating social improvisation and invention (Boudreau & Robey, 2005).

Sector C: Positive planned improvements to organizational performance can emerge. For example, the electronic submission and retrieval of documents has been used to improve service delivery (Yeo & Marquardt, 2015).

Sector D: Intentional imposed restrictions and monitoring controls can be implemented to impose standards and formalize practices. For example, in one case the requirement to store information in shared folders improved information access and also led to opportunities for collaboration through a virtual community (Yeo & Marquardt, 2015).

Figure 2. Impact of IT on organizations

Change	Enable	B: Invention	C: Improvements
	Inhibit	A: Workaround	D: Restrictions
		Unintentional Consequences	Intentional Consequences

The unintentional consequences arising from technology may result from both intended and unintended uses of technology by actors in the organization. For example, the inventive use of data entry fields overcame perceived limitations of the system but the misuse of data entry fields also leads to data quality issues (Bordreau & Robey, 2005).

Yeo & Marquardt (2015) suggest that enactment with technology leads to both innovation and disruption in work practices, which will impact organizational structure, strategy and performance. Technology can also lead to inequality and exclusion of some workers in the organization. The potential impact of technology adoption on organizations needs to be assessed to inform decisions about whether to implement the technology. Orlikowski (2007) criticizes studies of technology adoption that either adopt a techno-centric perspective of how technology impacts social practices, ignoring how technology is given meaning within a specific context, or adopt a human-centric perspective of how agents make sense of technology but implement a restricted view of technology. Orlikowski (2007) uses the term sociomateriality to refer to the emergent relationship between technology and human actors in the organization reflecting how technology loses its objective meaning as it becomes embedded in the social actions and practices of the actors in the organization. As actors make sense of the technology there is an interrelationship between the task and technology; the technology changes the task and the task changes the requirements and

use of the technology (Carroll & Rossen, 1992). Actors in the organization engage in collective sensemaking of technology (Yeo & Marquardt, 2015) and it is through this enactment of technology that organizations change (Bordreau & Robey, 2005). A framework is needed to explore how technology drives change in organizations.

SOLUTIONS AND RECOMMENDATIONS

Developments in IT provide new ways for organizations to interact with customers and other external parties, changing the external face of the organization. Organizations need a means to:

- Examine how the internal structures of the organization need to be adjusted to support the changes to the organization's external face.
- Assess the potential consequences arising from the internal changes proposed.
- Reflect on the impact the changes may have on the organization's identity.

The organization architecture provides an abstraction of organizational factors that influence an organization's IT development capability (Sherif *et al.*, 2013). IT can in turn also influence these factors in the organization architecture to lead change in the organization.

Organizations change over time, going through a series of phases of change. Cox *et al.*, (2006)

examined two cases of organizational transformation. The first case examined the organizational impact on a UK manufacturer following the implementation of e-business systems enabling collaboration between the manufacturer and the major supermarket chains. The second case explored the manufacturer's engagement in e-business with smaller retailers and the impact on the retailers. From these cases, eight dimensions of organizational transformation were identified, shown in the first column of Table 1.

These dimensions were also identified in analysis of the phases of change of a typical retail organization in the UK (Cox, 2014) as it moved from:

- Counter service (where customers asked staff for goods over a counter) to self service (where customers took goods from shelves and paid at a checkout before leaving the store).

- Self service to Internet service as customers purchased goods online.
- Internet service to Internet collaboration, as customers engaged in online communication with the store.

As the organization moved through these phases of change, the dimensions of change of the organization are shown in Table 1. This third case study is significant as it revealed that non-IT related change (the move from counter service to self service in the store) affected the same dimensions of the organization as the technology-related change (such as the introduction of online retailing).

Analysis of these dimensions showed that some of the dimensions related to formal components of the organization such as its infrastructure and security, and some elements referred to informal components such as trust.

Table 1. Morphing dimensions of a retail organization

Dimension	Counter Service to Self Service	Self Service to Internet Service	Internet Service to Internet Collaboration
People	Roles redefined.	Procedural roles, lacking flexibility.	Collaborative roles working with others online.
Skills	Broader and less specialized knowledge needed.	Less personal, online communication skills needed.	Develop relationships through ability to communicate online.
Practices	Way of shopping changed for customers and staff.	Way of shopping changed for customers and staff.	Information shared through working in partnership.
Processes	Front office processes changed: sales, purchasing and payment changed.	Back office processes changed: stock control, packing and distribution.	Front office processes to facilitate collaboration and back office processes to act on data captured changed.
Trust	Customers trusted to pay for items before leaving store.	Organization trusted to provide accurate shopping data, honour transaction and keep personal data secure.	Customers and organizations trust that data are accurate and not misused.
Data	Better product labelling needed on shelves.	Accurate data needed about the product, shopping process and terms of sale.	Challenges of technical capability and semantic issues arose.
Security	Risks to product security increased as customers had direct access to stock.	Risks to information security increased and security focuses on restricting access to information and transactions rather than physical products.	Security focuses on enabling legitimate access to information and communications.
Infrastructure	Shelving and counters in store changed style and placement.	Technical infrastructure development.	Compatibility and integration of data systems required.

The findings from these case studies were compared with the components of the 7-s framework (Peters & Waterman Jr., 2004) in Table 2. Although some overlap in areas such as staff and skills was identified, the analysis of the case studies highlighted more practice-based issues from the perspective of the staff affected by the organizational change. A key component that is not included in the 7-S framework is consideration to the changes to data and information in the organization and the role of data and information in the change process, which are particularly important in IT-led change. Table 1 shows how issues of data, security and trust were identified as key components affected by IT-related changes in the organization.

A further case study was conducted exploring the impact of e-business in a UK organization (Cox, 2013). This led to further refinement of the

organizational components affected by e-business. This list was then used to plan the introduction of social media systems in an organization taking into account the impact on the organization. In these five cases, the organizational structure was not directly affected by the e-business and social media systems introduced into the organizations. This led to the development of the dimensions to form the components in the organization architecture in Figure 3, which includes the elements of business architecture and infrastructure architecture of Sherif *et al.*, (2013). Referents of identity are different in each organization but the organization architecture provides a general framework in which to assess organizational transformation and the potential impact on organization identity. Components of the organization architecture are embedded in the culture and values of the orga-

ization, shown in Figure 3. Change to the organization architecture can be triggered by change to any of the architecture's components. Before a component in the architecture is changed, the morphing organization will need to consider to what extent the change aligns with the organization's culture or challenges its identity.

The organization architecture provides a framework to explore how changes to one component such as technology lead to changes of other components in the organization and whether changes to a specific component are consistent with the organization's identity. For example, the introduction of social media technology changed

the organization strategy and vision in terms of how the organization related to its external stakeholders in case study 5. The introduction of social media changed communication processes and practices, increasing threats to data security requiring additional software controls to be introduced. The organization had to trust that staff would not disclose confidential information through social media. As social media was integrated into existing systems and processes as another communication mechanism, staff needed to develop new skills in using the media. One of the organization's core values was consistency; consistency in information and service. The introduction of social media challenged this value as in responding to social media messages quickly, staff mistakenly published inconsistent information to customers. Technology is situated within the culture of organizations and has to be used in ways consistent with the organization's values in order to ensure that the organization's identity is maintained.

FUTURE RESEARCH DIRECTIONS

Organizational identity is an important concept, distinct from branding, to establish relationships between the organization and external stakeholders. As trade and communication is increasingly mediated by Internet technologies, further work is needed to establish how organizational identity is reflected, perceived and maintained through online activities. Organizations have been transformed and organizational identities have been challenged by developments in IT and by the speed with which IT has become embedded into society. As technology continues to become increasingly ubiquitous and the organizational boundary becomes blurred, the context in which technology is used by actors in the organization needs to be considered.

Porter & Heppelmann (2014) describe three waves of IT-driven transformation. The first wave focused on automating activities in the value chain, leading to the standardization of processes.

The second wave focused on co-ordinating and integrating activities in the value chain. A third wave of information IT-led change is now reshaping organizational and industry boundaries. The third wave integrates IT into products sold, capturing usage data about the product's functions and performance, enabling designs to be changed after products have been manufactured and sold. Porter & Heppelmann (2014) refer to the technology stack as the technology infrastructure needed to support smart connected products, comprising five levels: hardware, software applications, operating system, network communication and product cloud. Further understanding of organizational architectures is needed in order to explore how organizations can collaborate in the different levels of the technology stack to deliver smart connected products. As organizations collaborate within the technology stack, the impact on organizational identity needs to be considered.

CONCLUSION

IT has been used to lead organizational transformation, however, as actors in the organization seek to make sense of how the technology affects daily practices, technology becomes used in ways which were unintended. Boudreau & Robey (2005) therefore argue that as technology can result in unintended consequences, technology has a limited role in transforming organizations.

Technology forms one component of the organizational architecture. Change to any component in the organizational architecture has the potential to trigger change in other components. A framework has been presented, based on analysis of IT-led transformation in five case studies, to assist organizations in planning how a change in technology may affect other components of the organization architecture.

Porter and Heppelman (2014) suggest that organizations need to focus on the question, what business are we in? The business model helps organizations to explore the external face presented

to the trading environment. The organization architecture helps organizations to explore the internal components that sustain the organization's identity. Continued developments in technology will consistently challenge the shape, identity and practice of organizations. Further work is therefore needed to explore the longitudinal impact of changes to the organizational architecture and identity of morphing organizations within an ever changing technological context.

KEY TERMS AND DEFINITIONS

Business Model: An external representation of how the organization makes money and creates value through interactions with customers, suppliers and partners in the external trading environment.

Constitutive Entanglement: Complex configurations of inter-related concepts.

Context: The setting within which organizations, people, processes, information and events are interpreted. Context is an emergent property derived from interrelated dynamic states at a point in time.

Morphing Organization: An organization that changes the outer face the organization displays to the world by changing internal structures and processes within the organization to facilitate and support the external face, whilst seeking to maintain organizational identity.

Organization Architecture: An internal representation of the formal and informal components of the organization that provide the behavioural space for the organization's activities.

Organization Identity: A set of enduring attributes, which emerge through interaction with the organization, representing the spirit of the organization.

Organization Structure: The way in which resources are grouped in the organization to determine the control of activities, flow of information, and authority and responsibility for decision-making.

Organization Transformation: Significant changes to more than one component of the organization architecture that directly impact more than one department or function in the organization.

Sociomateriality: The view that technology and human interaction with technology are interlinked such that the two concepts cannot be objectively studied separately due to constitutive entanglement.

Workaround: A way of working to overcome perceived omissions, limitations or problems with formally defined working practices that are often embedded in IT systems.

How the Crowdsourcing Enhance the Co-Creation Into the Virtual Communities

B

Bahri Ammari Nedra
IHEC of Carthage, USA

INTRODUCTION

Nowadays, more and more companies are increasingly following the trend, by actively integrating their customers in their new processes of developing products and services (Romero et al. 2014). Co-creation is the process by which products, services and experiences are jointly developed by companies, their partners and the final consumer; leading to a new space where the created value would be shared (Prahalad and Ramaswamy, 2003). This form of cooperation has developed thanks to IT-based advances (IT) which promoted the development of social networks, blogs, forums and creative platforms (Peer et al. 2015). Many means that have allowed customers to interconnect with the world and to share, exchange, create and co-create knowledge (Lee et al, 2003). Through these new interconnected tools of socialization, customers can now actively contribute to the development of new products, ideas and concepts (Hoyer et al. 2010; Ogawa and Piller, 2006). Companies have soon realized its potential and seized the opportunity. Upstreaming or downstreaming the value chain, allowing for co-creation by costumers, resulted in customers as lead users (LU), simple users or emerging nature consumers (ENC). As such, customers represent a key to unlock new sources promoting competitive advantages for brands (Prahalad and Ramaswamy, 2004). By having access to brands' platforms, costumers could share their opinions about the product and experience. They could also discuss freely and participate in the evolution of the company's offer and develop its image and reputation. This is possible through crowdsourcing. This is

an online participatory activity that involves two parties: the user and the company / brand. The user will be satisfied by a given type of need, either, social recognition, self-esteem or development of individual skills, meanwhile the crowdsourcer will have the advantage of gaining what the user will bring to the company. Thus, some brands have found the way to keep their customers loyal while reducing the risks associated with creating a new product or service (Romero and Molina, 2011). In this line of thinking, the eYeka platform allows consumers and major brands to collaborate on creative projects and give in return an amount of money to the winning project.

However, the consequences / strategic implications of value co-creation were studied rigorously and prolifically, in terms of the cognitive, emotional and intentional patterns of co-creation. The aim of this paper is to determine the contribution of crowdsourcing in facilitating co-creation in virtual communities. And, *in fine*, to present the consequences of IT on firm, in terms of: the strength of the relationship, productivity, and efficiency.

BACKGROUND

Online Co-Creation: Definition of Co-Creation

According to O'Hern and Rindfleisch (2009), co-creation can be defined as "an activity of collaborative development of new products (NPD)¹ in which consumers actively contribute and select various elements of a new product offering" (p.86).

DOI: 10.4018/978-1-5225-2255-3.ch061

The recent literature pointed to the importance of integrating customers in the process of value creation as an effective way to develop better products while reducing the costs and risks of product / service failure (Prahalad and Ramaswamy, 2004). The concept of co-creation presents a new value form, something that is co-constructed, not just consumed by the customer. Co-creation, also known as participatory marketing or “consumer made”, is a new activity that refers to the participation of the customer as an active contributor from the start of the innovation process. It is a “situation in which consumers are working with companies to create value” (Humphreys and Grayson, 2008, p.963). In the value co-creation process, the customer can propose the company with innovative ideas for future products. In this regard, Sanders and Stappers, (2008) define co-creation as “any act of collective creativity, i.e. creativity that is shared by two or more people”. Similarly, co-creation involves customers in developing new products where they act as a source of innovation in order to increase the new product or service value. Indeed, it involves transforming the roles of the traditional players into Co-creators and co-responsible actors over time. Co-creation techniques refer to crowdsourcing or even collaborative or participatory marketing. The concept of co-creation is far from being simply customer-oriented. According to Prahalad and Ramaswamy, (2004), this tendency of the joint creation of products or services is a concept that shifts from a business-centric view to a product and experience-centric view of value co-creation.

Co-creating unique experiences with individual customers particularly helped to promote new sources of competitive advantage for companies. In this regard, several marketing researchers have investigated different facets of online Co-creation and its impact on business performance and the competitive advantage it may acquire. According to Zhuang (2010), co-creation is seen as a two-dimensional concept in which the customer may be considered either as a source or as a co-developer. Contrary to the approach that positions the cus-

tomers “outside the company”, the new approach places the customer within the company given the nature of the execution of value creation and innovation (Sahwney et al. 2005).

Co-Creation and Theoretical Trends in Marketing

Researchers show that the principle of co-creation has contributed to the emergence of several theoretical trends in marketing. We briefly mention the three main currents: tribal marketing, collaborative innovation and marketing Knowledge.

- *Tribal marketing or community marketing* (Cova, 2008). Tribal marketing builds on one central idea, which is the company’s losing some control over the brand for the benefit of the community of consumers seeking to reappropriate it (Brincker, 2003).
- *Collaborative innovation* includes three major concepts, namely “lead users”, “user innovation”, “user design” that were well developed by the work of Von Hippel (1978).
- *Knowledge marketing* considers consumer expertise, skills and intelligence allowing the company to define its offer and its production (Abidi-Barthe and Kaabachi, 2010).

VALUE CO CREATING WITHIN VIRTUAL BRAND COMMUNITY (VBC)

“Customer Empowerment”: Concept Presentation

Consumers dispose of limited tools to share their experiences and give their opinions. Today, with the emergence of Web 2.0, consumers have various means to share their passions, to know the opinion of others, and to produce and exchange content (Kozinet, 2002). They can quickly gather

information on the brand and its cost. In fact, they have more control over the use of information and are able to influence other consumers' purchasing decisions. This change has changed the relationship between consumers and businesses.

The advent of social web as a new creative space on the internet has redefined the role of the customer who becomes more involved in trade policy and corporate strategy (Füller et al. 2010). The customer wants to become a real "consum'actor" by being more involved in the company's value chain. He/she will interact with brands, shares the output power and contributes thus to the definition of the offer. He/she is not passive, he/she has become a key player in the marketing process (Firat and Venkatesh, 1993). The consumer is described as an actor more influential, more connected, more informed, more expert, more demanding and more active (Cova, 2008).

This shift in position contributed to the emergence of what is defined today as a "seizure of power" or "empowerment" of the consumer. This is a phenomenon involving the delegation of some power and empowering the consumer. The latter is considered a player who has more skills and is able to outsmart strategies and contribute to defining the guidelines and the company's shares (Cova, 2008).

Today, the customer is asked to design his/her own products, to conduct consumer arbitrations, model experience, either individually or with other people, and prepare for his/her favorite brand advertising (Xie et al. 2008). The consumer has taken the power to improve his/her knowledge of the business, which can procure satisfaction (Zwick et al. 2008). Managers will be invited to "take into account the other, the consumer, not learning about it, but learning from his/her, expertise, experiences..." (Cova, 2008, p.73). In this case, it is about doing marketing with consumers' "market with", instead of marketing to consumer "market to". A new collaborative perspective is established where the consumer is the business partner rather than the client. Value co-creation

(Prahalad and Ramaswamy, 2004) between the company and the (s) consumer (s) is thus the key process of this new marketing approach. Companies must, in this case, promote customized interactions and expertise and knowledge exchange with its customers. They must also rethink the way they conceptualize the brand and its image, think of a more collaborative approach in which value creation for the brand and its development is executed with consum'actors (Vargo et al. 2008).

The concept of empowerment refers to "co-constructed" marketing, considered the key to succeeding in maintaining long-term relationships and to effectively managing customer relationships (Filser and Vernet, 2011).

Forms of Value Co-Creation in Virtual Brand Communities (VBC)

Consumers' participation in value co-creation can take place upstream or downstream the production process. Upstream co-creation refers to customers' involvement before launching the product, while downstream co-creating focuses on looking to interact with customers after the purchase and use of the brand (Vargo et al. 2008). These two forms of participation were presented by Vernet and Hamdi-Kidar, (2010). They fully report to "customer empowerment":

Upstream Participation

- **Preconception:** The company involves creative consumers (lead users) in the design and development of new products to increase the efficiency of the new product development process and to reduce innovations cost. Companies are adopting preconception techniques to develop their imaginations and inspire new ideas for their brands. This is possible through exploiting the potential of the best customers endowed with expertise, intelligence and creativity. At this level, consumers are asked to respond to a given problem, and

to find a solution. They are requested to actively participate in the creation of new products, improved prototypes to test new products, and in the generation and evaluation of new ideas (Yan et al. 2014).

- **Mass Customization:** Consumers participate in an experience to change themselves certain elements of a product, specifying the attributes that best meet their preferences among a set of predefined modules by the company. This is done so that the final product is in line with customers' tastes and requirements. Consumers participating in product customization tend more to seek and develop positive attitudes towards the brand. Participation in product customization increases the level of consumer satisfaction, fosters brand loyalty and creates barriers against rebranding.
- **Co-Promotion:** Communities are increasingly wishing to be involved in the brand's life cycle and by means of involving themselves in designing an advertisement in accordance with the company's strategy. This is about involving the customer in developing communication policy. This contribution aims to promote and enhance brand image through the creation of advertising campaigns.

Downstream Participation

There are two forms of downstream participation are presented in Figure 1: co-production and co-determination (Cova, 2008).

- **Co-Production:** (User generated content) With the emergence of Web 2.0, "user generated content" has become one of the new trends in current marketing. Consumers share their stories and speak via virtual communities, post information, comments, and photos to share their experiences and give their opinions. The content is produced directly by users and helps to pro-

mote interaction between the company and users. This content creation by customers is a key element for developing brand awareness and influencing attitudes and behavior of other consumers.

- **Co-Determination:** Co-determination is granted when the company promotes cross-identification of needs between the company and the creative consumers. It is an open dialogue that should determine consumers' needs and expectations in an exploratory manner. The company can then use this information to readjust its offer and enjoys the consumption experience and generates the maximum of value. Companies are committed to this type of "participatory" marketing because they may gain several advantages.

Practical Online Value Co-Creation

Different forms online value co-creating may be distinguished, namely: crowd sourcing, open and user innovation.

Crowdsourcing

Crowdsourcing emerged in 2006 and was used to describe users' activities to co-create content. Crowdsourcing is the use of information using a host of technologies (eg, business, individual, organization) to outsource certain business tasks (Prpic' et al. 2015). Crowdsourcing demands concrete solutions to a problem or a specific task. Contributions can firstly be objective and well-founded and partly subjective and be required to perform tasks to determine users' opinions, tastes, or beliefs.

Crowdsourcing is an online participatory activity which an individual, an institution, a non-profit organization, or a company offers to a group of individuals with different knowledge, voluntary commitment to a task. The user will be satisfied with a given type of need, either, social recognition,

Figure 1. Managerial forms of consumer made

self-esteem or development of individual skills, meanwhile the crowdsourcer obtains and uses to their advantage what the user has brought to the company. This form will depend on business activity types (Estellés-Arolas and González-Ladron-de-Guevara, 2012).

Open Innovation

Changes brought by globalization have significantly influenced companies, which have become constantly seeking knowledge resources and expertise. Open innovation is to create and innovate with the support of external stakeholders: customers, suppliers, partners and the wider community. Open innovation therefore creates a space where individuals and organizations can be actively involved in the creation of mutually beneficial solutions. Open innovation is a social and inclusive way to solve complex issues and improve processes. It suggests contacting larger groups and it is based on community engagement to collaborate around specific challenges and issues. Thus, the flow of ideas from outside of the organization generates intelligent and innovative solutions within the organization.

User Innovation

User innovation refers to innovation by intermediate users (such as users, companies) or consumer users (end individual users or groups of users), rather than by suppliers (producers or manufacturers). Many products and services are developed or at least refined by users on the implementation and use phases. When most consumers have problems with products, users bring their own modifications to existing products or entirely new products. Often, users share their ideas with manufacturers hoping to innovate and participate in the production of the product. According to Tuomi (2002), the main uses are often not expected uses invented by the user communities, which reinterpret and reinvent the sense of emerging technological opportunities (open source software).

Figure 2. shows the position of crowdsourcing vis-a-vis open innovation and user innovation (Tuomi, 2002; Rayna et al. 2015; LaToza and Van-der-Hoek, 2016):

Figure 2. Positioning of Crowdsourcing

CONSEQUENCES OF CO CREATION

The Effects of Participating in Online Co-Creation

In this section, we will define and detail the implications of co-creation on consumer loyalty behavior, namely: electronic word-of-mouth (e-WOM), re-purchase and price tolerance.

E-WOM

E-WOM allows influencing the success or failure of marketing new products, sales volume, brand awareness and brand equity (Bambaur-Sasche, 2011). Word-of-mouth influences consumers' purchase decision. Indeed, comments circulated about the product significantly affect attitudes (Lee et al. 2003), purchase intent (Lin et al. 2013) and reduce purchase perceived risk. Thanks to E-WOM, cyberconsumers are the best sales force to build the brand and develop brand awareness and loyalty. Companies should make considerable efforts to encourage the implementation of positive word of mouth and accelerate its diffusion (Dellarocas, 2003).

Re-Purchase

Under a behavioral perspective, loyalty characterizes consumers who buy a special offer - whether

a product or service - and continue to buy, rather than switch products/services (Lin et al. 2013). "It refers to the behavior of consumers purchasing a brand for a period of time (Lin et al. 2013, p. 279)". Behavioral loyalty can be understood as a synonym to repeating a purchase behavior or a repeated purchases behavior.

However, to achieve a repeated purchase behavior, the consumer undergoes various interactions that determine their decisions. This brings us to discuss the relationship between emotions, brand engagement and loyalty behavior. First, we believe that customer engagement is considered a determinant of customer loyalty (Gundlach et al. 1995; Morgan and Hunt, 1994; Fullerton, 2003).

Price Tolerance

Price tolerance generally is considered as the situation consumers to be willing to accept an increase in prices without recourse to switching the product or brand. Thus, this consistency in customer behavior is called price tolerance. However, Anderson (1996) explains that price tolerance sets a limit above which the customer will switch brands or products. In addition, several authors have established a link between affective commitment and price tolerance, pointing to a significant relationship between affective commitment and price tolerance in e-commerce (Fullerton, 2003), and proving the positive effect of affective com-

mitment on consumers' willingness to pay more for a service.

Strength of the Relationship

Strength of the relationship is often defined as *"the extent and degree of the relationship"* (Bove and Johnson, 2006). It amounts to the creation of a better value for the customer, while involving customers in the process. It is considered the basis for the development of long term relationships with customers. It should be mentioned also that co-creation through customized interactions and specific customized problem-solving solutions can strengthen more buyer-seller relationships (Claycomb and Martin, 2001). Evanschitzky et al. (2006) argue that strong buyer-seller relationships contribute to customer loyalty. Therefore, interaction and dialogue resulting from co-creation is conducive to strong buyer-seller relationships. Indeed, business-customer relationships can be strengthened by co-creation, which in turn improves customer equity (Kumar et al. 2010; Van-Doorn et al. 2010).

Typology of Co-Creation Activities

A conceptual typology of customer co-creation should positively contribute to building and strengthening relationships between companies and customers during the innovation process. This typology depends on the nature of provided information.

The first dimension rests on the nature of provided information. In every innovation process, companies face uncertain sources with regard to their technical and managerial capacities. To re-

duce these uncertainties, companies need to have access to different types of information which is divided into two groups and presented in Figure 3 (Ogawa and Piller, 2006; Von-Hippel, 1986):

- Information on customer needs and market (needs information): i.e. information about preferences, needs, desires, satisfaction, motivations... This information allows the company to better understand customer requirements and reduce failure risk.
- Information on technical solutions, and in particular on how to use technology to transform customer needs in view of offering a new product / service. Access to this type of information allows product developers to put in place resolution activities more oriented towards the innovation process.

Information distinguishes co-creation methods into "money markets" based on economic relationships with monetary incentives, and "social market" methods based on social exchange relationships with non-monetary rewards (Füller, 2010):

- Economic exchange is based on a monetary exchange of ideas against solutions. Participants compete to get the maximum from a limited allocation of resources.
- Social exchange consists of methods with which participants engage in innovative behavior for reasons such as pleasure of completing the task, or expectations of results that enhance their own usage experience (Harhoff et al. 2003).

Figure 3. Typology of co-creation activities

Three types of opportunities of value co-creation are distinguished (Payne et al. 2008; Storbacka et al. 1995): opportunities offered by technology, by industry changes and customer preferences changes.

- Opportunities offered by technology (e.g. iPod) provide companies with new methods to: engage with customers, co-create innovative goods / services and enjoy the experience offered.
- Opportunities offered by changes in customer preferences and lifestyles. In this regard, companies should constantly detect new preferences, new lifestyles...

Challenges to Co-Creation

The company can create two important sources of competitive advantage through the implementation and good management of co-creation: productivity gains and improved efficiency (Payne et al. 2008; Storbacka et al. 1995).

Productivity Gains

Co-creation allows the brand to increase its productivity gains and efficiency. Consumer input in the development of products and services reduced certain internal costs to a minimum (Gatautis and Vitkauskaitė, 2014). Indeed, this contribution will partially replace the work done by employees. Cost reduction also results from a gain in acquiring certain information and studying consumers. Co-creation also allows the brand to be more efficient in its market by reducing failure risk of its products through the continuous improvement of products and the response speed to the market (Xie et al. 2008).

Improved Efficiency

Co-creation can bring significant gains in efficiency in co-creating products, through a better alignment of consumer needs and their high commercial potential (Lilien et al. 2002). These results can directly influence product / service

sales, employee satisfaction, organizational performance, increase operational efficiency and ultimately, revenue / profitability. Co-created products differ from other products (Song and Adams 1993), have better commercial attractiveness (Franke et al. 2006) and generate high expected benefits. In addition, adjusting products / services preferences to co-creation can increase positive attitudes toward the product, subsequent purchase intentions, and willingness to pay more and positive word-of-mouth about the brand (Keinz and Steger, 2009). Thus, co-creation can strengthen business / customers relationships, improve customer capital through increased delivery of value and an increasing number of connecting points between the company and consumers (Van-Doorn et al. 2010; Tong et al. 2014). Companies in the same market are able to aggressively compete to attract and retain the most important co-creators.

FUTURE RESEARCH DIRECTIONS

Web 2.0 has facilitated the work of brand managers and enabled consumers to be more active and more involved on the net. However, some issues are to be mentioned that call for special attention. First, we need to identify the factors that motivate users to participate in co-creation in order to control them. Second, we should think of criteria to assess participants' skills in co-creation? This issue is very relevant as consumers who participate should be very effective in co-creation. Moreover, it would be best to determine which application of crowdsourcing applies to which target / population? Third, we should determine the nature of the relationship between brands and consumers. How it should be and what are the determinants that strengthen this relationship and how to control them?

CONCLUSION

Today, more than 40 million people worldwide participate in a virtual community (Sicilia and Palazon, 2008). These people are becoming more demanding vis-à-vis the products and services offered by companies. Given the competitive environment, companies put customers at the heart of their strategies to best meet their expectations.

The concept of co-creation was created to engage the customer, whose aim, for the company, is to create new opportunities and gain competitive advantages in the market. First, it helps to generate positive word of mouth about the brand and participatory operations perceived as original. This strategy can reach a wide audience to increase awareness, recruit new customers, and increase sales. Developing interactivity with the consumer is a part of the brand's objectives. Indeed, brands are creating connecting opportunities with customers to better understand consumers, better meet their expectations and improve the relevance of innovations. The more individuals contribute to the generation of content, the better the company identifies their needs and desires.

Involving consumers in value co-creation makes the brand more salient and memorable and strengthens brand / consumer proximity. Integrating the consumer in a co-creation process promotes customer self-identification with the community and insures their loyalty in the long-run (Algesheimer et al. 2005). Participatory marketing allows the company to benefit from the consumers' creativity and reduce research and development costs.

KEY TERMS AND DEFINITIONS

Co-Creation: Co-creation is the process by which products, services and experiences are jointly developed by companies, their partners and the final consumer, leading to a new space where the value created would be shared.

Crowdsourcing: This is a participatory activity online that involves two parties: the user and the company / brand.

ENC: Consumers capable of developing any product that the ordinary consumer will find more attractive and useful as those developed by the LU. Lead users are users who, through their

experience, their expertise and their know-how in one area have a real attention from firms.

E-WOM: Any positive or negative statement made by a potential customer and is available to a multitude of consumers through the Internet. E-WOM promotes faster diffusion of information among members of a community. Moreover, it is the basis of a viral effect likely to cover a wider audience and contribute to developing or damaging brand image.

LU: Lead users are users who, through their experience, their expertise and their know-how in one area have a real attention from brands.

Virtual Brand Community (VBC): The place where consumers identify with the group they belong to, and who are actively involved in value co-creation and in the interactive exchange of opinions on online platforms in order to contribute to the development of the brand image (Peer et al. 2015).

Web 2.0: Allows, through a set of simple tools, better interactivity between users / user. It is for them to exchange information and interact in a simple way to create and share content on the web. The user becomes more active on the web and contributes to the enrichment of social networks by providing useful information for brands/firms.

¹ NPD: New Product Development

Hyper-Sensitivity in Global Virtual Teams

Andre Araujo

Texas A&M University, USA

INTRODUCTION

Increasingly multinational enterprises are implementing global virtual teams. In such online collaborative settings, developing shared understanding and managing interpersonal conflict may be constrained by the fact that members have little of the traditional mechanisms that are used to engage in personal interactions with others, observe fellow team members at work, or develop a shared history of professional accomplishments. In addition, members of virtual teams may be thousands miles away from each other and possess different cultural background. Due to the absence of proximal interactions, virtual team members are likely to evaluate others based on amplified perceptions of their computer-mediated social interaction (Walther, 1996). This chapter examines hyper-sensitivity in virtual teams and its consequences to team's relational interactions and outcomes. Specifically, the following research question is addressed: *What are the mechanisms that influence levels of engagement and interpersonal conflict in global virtual teams?*

BACKGROUND

Typically, global virtual teams employ web-based collaboration tools such as Trello, Basecamp, and Sync.in, to name a few (Gilson, Vartiainen, & Hakonen, 2015). While recent web-based technologies provide a great deal of functionalities, anecdotal and empirical evidence suggest a number of challenges faced by teams who rely on computer-based technologies to communicate

and accomplish their tasks. Some of the challenges include overcoming isolation among team members, cultural differences, less time for relationship building, lack of participation, conflict management, and building trust.

This chapter broadens our understanding of this phenomenon by integrating two theoretical approaches—the Hyper-personal Perspective and the Social Constructionist Theory—to examine how members of global virtual teams develop relational interactions. Specifically, the integrated research model presented here suggests that global virtual team members are hyper-sensitive to their computer-mediated interpersonal interactions in that individuals' socially constructed perceptions of the context influence their relational development and judgments much more intensively than those of collocated members.

In this study, the key components of the context are the task-at-hand and shared identity, while relational interactions are defined in terms of interpersonal conflict and level of engagement. Thus, how members of global virtual teams perceive their task and their team will profoundly affect their relational interactions, including how much conflict they experience and how engaged they view their team members as being. Over time, the amplification of these affective elements will affect their judgments about their fellow members' trustworthiness. The main components of our research model and its relationships are depicted in the Figure 1. In the following sections we describe the research model (Figure 1), its components, and their combined impact on relational interactions in global virtual teams.

Figure 1. The research model

RESEARCH MODEL

The Hyper-Personal Perspective

Walther (1996) suggests that the meaning inherent in messages is amplified when individuals have limited physical contact with each other and therefore develop perceptions about others and their relationships based on the available mechanisms at hand, e.g., electronic communication exchanges. In other words, in computer-mediated settings, any piece of information exchanged between team members is likely to take on a significance of its own and is subject to over attribution.

This perspective helps explain why members of distributed groups have the potential to profoundly amplify interpersonal exchanges between the sender and receiver, thereby offering important insights to relational development in virtual teams. For instance, Jones (1995) reported that individuals who participated in online groups exhibited feelings of closeness due to the warmth conveyed in their communication exchanges, compared to collocated groups even though the virtual context would imply physical isolation. These results suggest that members of virtual teams enhanced the meaning of their communication exchanges (beyond the mere messages), thereby enabling them to develop emotional ties that exceeded those in collocated settings.

Social Constructionist Theory

The social constructionist perspective suggests that human social order is produced through interpersonal negotiations and implicit understandings that are built up via shared stories and experiences (Berger & Luckman, 1966). Thus, beliefs held by members of a group determine to what extent meanings of terms are invented and sustained. In other words, how members interpret their context and social interaction processes helps to predict individual cognitions and behavior. An important aspect of the social constructionist approach is its distinction between objective and subjective reality. While the objective reality refers to facts of everyday life that are real or apparent to those who 'inhabit' it, the subjective reality is constructed and reproduced over time. Consequently, given that these subjective interpersonal perceptions help to define reality, perceptions developed over time by members of work groups influence how individuals "objectify" organizational elements around them.

When applying social constructionist notions to virtual teams, "reality" is realized through interpretation whereby team members develop patterns of meanings from their electronic interactions with others. In other words, members' views and perceptions in computer-mediated settings evolve and change over time (Walther, 1996)

based on how they interpret or make sense of their social interactions, which then helps define their reality. To sum up, members will develop socially constructed perceptions of the computer-mediated context based on how they interpret or make sense of their task and team. These social constructions will influence their behavior, and in turn, influence their relational interactions.

THEORETICAL PROPOSITIONS

Drawing upon the previous discussion, we establish the central tenet of our thesis: Global virtual team members will develop perceptions regarding their task and team. These socially constructed perceptions will influence their relational experiences, which, in turn, will impact their judgments about their fellow members' trustworthiness. Furthermore, the hyper-personal perspective suggests that these relationships will be stronger in virtual teams (in comparison to collocated teams) because their members are likely to amplify communication exchanges in the absence of other stimuli (present in collocated teams). The model is depicted in Figure 1 and the variables comprising it are described below.

Perceptions of the Task: An extensive body of research has dealt with the effects of different types of task on group work (Benbasat & Lim, 1993; McGrath, Arrow, Gruenfeld, Hollingshead, & Oconnor, 1993). In general, these studies have defined task as an objective input variable, which then impacts group members' behavior and performance McGrath (1984). Such an approach ignores members' subjective perceptions of the task, which are based on member's sense making processes that evolve over time (Berger & Luckman, 1966). In this sense, behavioral requirements of the task are not conceived as physical characteristics; rather they are viewed as the members' interpretation of what needs to be accomplished (Hackman & Vidmar, 1970).

Consider, for example, the working processes of two teams. A member of one team could inter-

pret a cooperative task [as defined in McGrath's (1984) task circumplex] as requiring conflictive behavior, if, during group interaction, members engage in frequent disagreements or sharp exchanges. Conversely, a conflictive task [as defined in McGrath's (1984) task circumplex] may be interpreted as requiring cooperative behavior if a group member perceives members as sharing their ideas freely and operating in a climate of mutual understanding. Drawn upon these arguments we define *perceptions of the task as a contextual element that is susceptible to interpretation and reinterpretation and may vary as the result of an individual's social interactions.*

Level of Engagement: It refers to the extent to which group members are viewed as being responsive to the needs of the group and reflects the extent of reciprocal interaction among team members (Kramer, 1999). Research suggests that members' perceptions of continuous involvement by and interaction with others help to build trust relationships over time (Rousseau, Sitkin, Burt, & Camerer, 1998). Additionally, in the context of virtual teams, the effects of responsiveness are even more salient because the level of engagement is based on members posting and responding to messages over time (Gefen & Ridings, 2002). Based on these notions, we define *level of engagement as the extent to which members of global virtual teams see their virtual counterparts as being responsive to the needs of the team as they interact through computer-mediate technologies.*

In most group settings, a significant amount of members' efforts involve activities critical to the effectiveness and well-being of the group. Therefore, it is likely that members perceiving their task as being a cooperative venture will engage in more frequent interactions and exchanges with their partners, i.e., be more responsive to the needs of the team. As a result, cooperative perceptions of the task are likely to positively influence the level of engagement in group interactions. Furthermore, as discussed earlier, in the virtual context most of the communication exchanged between partners is done electronically; hence, virtual teams are

likely to over attribute their impressions about contextual structures compared to collocated teams. Thus, how the task is perceived is likely to have a particularly strong effect on members' engagement in virtual teams. Hence, we propose:

P1a: Perceptions of the task will be more related to the level of engagement in global virtual teams than in collocated teams.

Interpersonal Conflict: Interpersonal conflict is targeted at persons within the group and can be detrimental to group work by increasing the intensity of negative attitudes toward others (Deutsch, 1969). Consequently, it can impede trust development and hinder group performance (Jehn & Mannix, 2001). Furthermore, the negative effects of interpersonal conflict may be perceptible even more keenly in virtual teams because their meetings have fewer structural mechanisms that enable them to interpret member's behavior and attitudes over time (Nunamaker, Applegate, & Konsynski, 1988). Hence, we define *interpersonal conflict as the extent to which individuals perceive clashes among team members when working in a global virtual setting*.

A social constructionist view suggests that a member's perceptions of the task will influence how they view fellow members and the ensuing relationships (Yang & Mossholder, 2004). Additionally, given that groups spend considerable time focusing on the task at hand (McGrath, 1991), task type is likely to be a critical factor in understanding relational dimensions such as interpersonal conflict (Jehn, Northcraft, & Neale, 1999). Accordingly, tasks perceived as being cooperative suggest a context where members are likely to perceive their partners as being on the same side, collaborating and helping each other in order to achieve a common goal. Hence, members are likely to develop positive perceptions of their partners, which will reduce interpersonal conflict (Jehn & Mannix, 2001). Conversely, tasks perceived as being contentious implies a context where members see their partners as adversar-

ies. In this context, members are likely to have difficulty developing relational ties and conflict levels are likely to rise. Moreover, as discussed earlier, individuals working in the virtual context are likely to rely greatly on their communication exchanges in developing affective relationships; hence, perceptions of their environment, including the task, will more intensely affect their social interaction processes compared to collocated groups (Walther, 1996). In other words, given the hyper-sensitivity of virtual teams, the positive (or negative) effects of members' perceptions about the task will carry over to their online relationships, including interpersonal conflict. Thus, we propose:

- **P1b:** Perceptions of the task will be more related to interpersonal conflict in global virtual teams than in collocated teams.

Shared Identity: According to Social Identity Theory (Hogg & Terry, 2000; Tajfel, 1978; Turner, 1985) members categorize themselves as well as those around them into two distinct groups: in-group or out-group. Members perceive themselves as being 'ingroup' when they perceive their partners as sharing common values, beliefs, and attitudes as they engage in group interactions over time. Based on these assumptions, *shared identity refers to the extent which an individual identifies with his or her team members when working in a global virtual setting*.

Shared identity has been shown to impact other aspects of group interaction such as members' levels of engagement. Social psychologists have suggested that individuals tend to communicate more, and are more likely to interact with those perceived as sharing a common set of values and work goals. In addition, positive group identity motivates individuals to be more cooperative with others because group membership is likely to increase attachment to and embeddedness with the group (Yang & Mossholder, 2004). In other words, group members who perceive themselves as being part of the group are likely to engage

in frequent interactions with their partners in an effort to remain connected to the group.

Conversely, low levels of shared identity in groups result in reduced communication and coordination (Ancona & Chong, 1996). In virtual contexts, the reduced communication and coordination processes result in members replying to others' requests sporadically. For example, Grinter, Herbsleb, and Perry (1999) found that members of distributed software development teams constantly misinterpreted the activities of their distant colleagues due to the reduced level of communication and lack of coordination among members. Thus, the lack of shared identity appears to lower members' engagement with the group and its activities. Given the earlier discussion about hyper-sensitivity in virtual teams, members of these teams are likely to experience heightened effects of shared identity on levels of engagement in comparison to collocated teams. Hence, we present:

- **P2a:** Shared identity will be more related to the level of members' engagement in global virtual teams than in collocated teams.

A strong body of research indicates that members' evaluations of others actions and behaviors are influenced by their views of shared group identity (Levine & Moreland, 1990). These social mechanisms act as interpretation processes through which group members make sense of their activities (Berger & Luckman, 1966). For instance, many theorists (Hogg & Terry, 2000; Tajfel, 1978; Turner, 1985) suggest that perceptions of shared identity are likely to be closely related to positive evaluations of group members. These positive effects result from the fact that perceptions of increased "groupness" are related to members' perceptions that their attitudes and behavior are similar to those of others in the group (Hogg & Terry, 2000). In other words, individuals tend to evaluate others' actions more positively when they feel that they share common values

and goals. Conversely, in the absence of shared values, team members are likely to have trouble affiliating. Viewed differently, stronger perceptions of shared identity are likely to dampen the development of interpersonal conflict (Jehn et al., 1999; Mortensen & Hinds, 2001). Moreover, given the arguments of hyper-sensitivity, the perceptions of "groupness" may be particularly salient in contexts where no physical contact exists (Lea & Spears, 1991). Hence, we propose:

- **P2b:** Shared identity will be more related to interpersonal conflict in global virtual teams than in collocated teams.

FUTURE RESEARCH DIRECTIONS

The model developed in this study suggests that the beliefs held by group members about contextual variables such as the task-at-hand and shared identity have a differential impact on their relational interactions based on the setting. In collocated settings, where members have the ability to engage in various forms of communication and thus have competing or converging inputs for evaluation, members' perceptions of the task plays only a minor role in shaping their relationships. However, in global virtual settings, where members have to deal with the effects of the geographical distance and thus have fewer mechanisms to observe and evaluate their relational interactions, individuals give greater weight to their perceptions of the computer-mediated work context. These perceptions, in turn, are likely to affect the formation of social ties significantly.

While we expect to test the relationships detailed in the model in future research, the propositions have several practical implications for managing global virtual teams. First, members of such teams can get their work done remotely without having to meet up, anchored to a specific location such as a country, an organizational setting, or a local office. However, often it is difficult for members with different nationalities to

understand each other due to language and cultural differences. In this context, communication is vital for the team's success. Thus, managers may consider employing web-based technologies that enhance cross-cultural communication and team building relationships. For example, tools such as video conferencing and instantaneous message systems may enhance team's ability to monitor and track a project by providing real-time interaction among team members. These tools may ultimately help team members to quickly develop relational interactions since they enable the conveyance of subjective meanings such as tone of voice, facial expressions, and efforts spent toward the completion of the task. In contrast, managers should be careful when implementing asynchronous tools such as emails because they may lead to confusion and frustration due to the fact that co-workers are likely to exchange back-and-forth messages trying to understand subjective meanings attached to each message.

Second, our propositions suggest that level of a member's engagement in group activities is critical to the development of positive perceptions about its peers. Thus, managers should carefully select web-based tools that support activities such as planning, time management, and meeting scheduling. These tools are likely to allow different members of the team to update their specific areas of the project, allowing everyone to see the changes as the project progresses, teams can create regularly scheduled online meetings so that members can avoid wasting time trying to interpret other's input to the task.

Third, the model implies that the reliance on technology to communicate with others and the effects of the distance that separates members can exacerbate negative interactions and emotions, whereby team members tend to over attribute meaning to the information contained in computer-mediated messages. One promising technology to enhance team work and perhaps minimize negative meaning attached to limited text-based messages is cloud computing. Given that members are geographically dispersed and have a number

of other organizational activities outside of their team project, individuals often have limited time to meet to be able to discuss their progress. This is where cloud systems come into play. Managers may use cloud computing resources to set up a platform that lets individuals log in to a central repository of data and documents. This would allow team members to access and share files from different locations at any time. In addition, the repository may contain a history of group communication and relevant task information, which, in turn, allows members to capture, store, and visualize members' interactions and contributions to the task at a hand. In addition, teams can work on the project from where ever they are on their portable devices (without relying to any specific local server) and still get the job done.

From a research perspective this study offers a number of insights for future research. First, scholars interested in examining social components affecting team performance in global virtual teams may consider testing the relationships depicted in our model in longitudinal studies. For example, our model suggests that the effects of technologies on group work should not be divorced from the processes that emerge as individuals use these technologies and construct perceptions about their ongoing interactions over time. The impact of these tools may have a differential effect on individuals' perceptions as teams interact over time. Therefore, longitudinal studies can incorporate the effects of time to examine how these relationships unfold as the team progresses in their assigned task.

CONCLUSION

The purpose of this study was to explore the mechanisms that influence levels of engagement, interpersonal conflict, and trust in global virtual teams. Overall, the model supports the idea of hyper-sensitivity in virtual teams by suggesting that perceptions of the context influence their ongoing interaction processes in ways that exceed those of collocated teams. In other words, in the absence

of physical proximity, members gave primacy to their available sources of information—such as perceptions of their task, which then informs their ongoing interactions with others. These interactions, defined by interpersonal conflict, then color their judgments about others, including trust. The detrimental effects of interpersonal conflict on the development of trust suggest that negative relational interactions in virtual teams have a more serious effect on trust development (than in the comparable collocated setting).

Furthermore, in global virtual teams, perceptions of the task are likely to have an inverse relationship with interpersonal conflict. In addition, perceptions of the task are expected to have an amplified effect on the level of members' engagement during group interaction in the global virtual teams. This relationship is expected to be weaker in the collocated teams. Taken together, these propositions support the social constructionist view of virtual work in that how the task is viewed affects members' relational ties and evaluations of their peers—in some settings. In other words, in the absence of a collocated social context, members of a virtual team may pay more attention to the actual messages exchanged through their text-based interaction, rather than multidimensionally evaluating the socio-emotional climate of their context.

While contextual elements are likely to impact members' relational interactions and behavior, how individuals 'objectify' these structures defines their social interactions. Our findings support the idea of hyper-sensitivity in virtual teams, which tend to experience a disproportionately greater effect of task perceptions on social interactions compared to their collocated counterparts. Thus, the hyper-personal perspective serves a vital function by enabling virtual teams to make sense of their environment using the available information and engaging in the process of relational development.

KEY TERMS AND DEFINITIONS

Hyper-Sensitivity Perspective: This perspective helps explain why members of distributed groups have the potential to profoundly amplify interpersonal exchanges between the sender and receiver

Interpersonal Conflict: Refers to the extent to which individuals perceive clashes among team members when working in a global virtual setting. Typically, it is detrimental to group work by increasing the intensity of negative attitudes toward others.

Level of Engagement: Refers to the extent to which members of global virtual teams see their virtual counterparts as being responsive to the needs of the team as they interact through computer-mediate technologies.

Perceptions of the Task: It is a contextual element that is susceptible to interpretation and reinterpretation and may vary as the result of an individual's social interactions.

Shared Identity: It refers to the extent which an individual identifies with his or her team members when working in a global virtual setting.

Social Constructionist Perspective: It suggests that human social order is produced through interpersonal negotiations and implicit understandings that are built up via shared stories and experiences (Berger and Luckman, 1967). Thus, beliefs held by members of a group determine to what extent meanings of terms are invented and sustained. In other words, how members interpret their context and social interaction processes helps to predict individual cognitions and behavior.

Lean and Six Sigma Innovation and Design

B

Rick Edgeman

Utah State University, USA

INTRODUCTION

Six Sigma Innovation and Design theory, strategy and supporting methods have evolved along two primary pathways – one focused on significant innovation of existing products, services, processes or systems, and a second focused on design of new products, services, products or systems. A third, more recently emerged path is referred to as LSS or *Lean Six Sigma* (Pepper & Spedding, 2010). LSS integrates and leverages the sizeable commonalities, synergies and strengths of Six Sigma and Lean Enterprise theory and methods while ameliorating their weaknesses and distinctions. In particular, LSS wedges key lean methodologies and perspectives such as value stream mapping, kaizen (continuous improvement), and waste identification and minimization together with equally key Six Sigma concepts and tools such as its focused approaches to innovation and design – DMAIC and DMADV.

Six Sigma in the late 1970s at Motorola Corporation, but it is GE with which Six Sigma is most familiarly associated. Its use has proliferated due in large to its acknowledged contribution of multiple billions of dollars to the economic performance of many enterprises. Six Sigma delivers either desirable and reliable new designs or significant improvements in existing products, processes, systems of key importance to customers or – more generally – to relevant enterprise stakeholders. This is accomplished by identifying and subsequently exacting change in key measurable and internally controllable levers of change that drive outputs highly relevant to those stakeholders. Such outputs are referred to as critical-to-quality (CTQ) characteristics and directly reflect preferences of customers of the product, process or systems

that is being addressed. It is because we cannot directly control these CTQs that we must instead identify and control levers of change. Doing so begins with a clear and elaborated definition and understanding of customer and other relevant stakeholder needs, desires, and expectations – the so-called voice of the customer (VOC).

Lean Enterprise theory and approaches are often associated with Toyota Corporation and the familiar *Toyota Production System* (TPS) credited to late Toyota executive Taiichi Ohno and his mentor, Shigeo Shingo (Schmenner, 2015). Lean Enterprise methods are also associated with Kaizen (continuous improvement) philosophy and methods popularized by Masaki Imai (Antony, 2015). The arc of Lean Enterprise projects and enterprises is one typically aimed at waste reduction leading to improved efficiency, increased reliability, enhanced design, and better resource utilization so that such projects tend to be internally-focused, with derivative value for the customer.

Both Six Sigma and Lean Enterprise emphasize near relentless pursuit of perfection. Lean Enterprise methods do so via continuous incremental improvement cycles with an eye toward all enterprise processes and activities. In contrast, Six Sigma projects are typically discrete in nature and target breakthrough improvement in strategically important processes, products or systems. As such, the union of Lean Enterprise with Six Sigma is both internally and customer focused, taking simultaneous aim at both cost savings and value creation.

Six Sigma Innovation, Design for Six Sigma, Lean Enterprise and – more specifically – their integration that resulting in Lean Six Sigma are discussed. Although each of these has been his-

DOI: 10.4018/978-1-5225-2255-3.ch063

torically emphasized financial objectives, in principle they be used to singly or jointly address any number of objectives, including financial, social, or ecological performance, or anything contributing to organizational resilience and robustness (Edgeman, 2013). Also discussed are distinctions between the COPIS approach to business process conception prior to process implementation and execution via SIPOC (Edgeman, 2011a); commonly used supporting tools and techniques such as the Kano Needs Model and Quality Function Deployment or QFD (Tan & Shen, 2010); and concept generation and selection (Girotra, Terwiesch and Ulrich, 2010).

BACKGROUND

Of many competing Six Sigma and Lean Six Sigma definitions, the following, adapted from Klefsjö, Bergquist and Edgeman (2006), is herein employed:

Lean Six Sigma provides highly structured innovation, design, and lean enterprise strategies and methods for acquiring, assessing, and activating customer, competitor, and enterprise intelligence in order to deliver superior product, process, system, or enterprise performance that benefits all relevant stakeholders through best and next best practices and sources of sustainable competitive advantage.

Six Sigma is not unique in this quest for exceptional performance and competitive advantage. Rather, it is the combination of Six Sigma's strategic focus, structured approaches, breakthrough performance levels sought, and relatively short time horizons within which such improvement is demanded that distinguish it from other improvement, design, and innovation approaches.

Six Sigma's is provided by its focused design and innovation approaches. Its focused innovation algorithm is referred to as DMAIC and is a simple, yet logical scheme that demands the

project in question to be carefully defined (D), with definition followed by measurement (M), analysis (A), improvement (I), and control (C) phases. Design for Six Sigma (DFSS) projects may employ any of a number of approaches, with the most common being DMADV, an acronym for Define-Measure-Analyze-Design-Verify (Edgeman, 2011b). While there are similarities between DMAIC and DMADV, there are also key differences, including in the intentions behind Define, Measure and Analyze in these algorithms (Cronemyr, 2007).

Specific content of each step in DMAIC and DMADV depends on enterprise and competitive context, the knowledge array resident in project team members, and the disciplinary traditions of those team members. Superior performance may be defined in absolute terms or specific to competitive context. Sustainable competitive advantage often relies not on application of Six Sigma or other strategies per se, but rather on enterprise enculturation and the effective and efficient use of such approaches in areas of strategic importance.

The need to significantly improve product and process performance through innovation provided much of the initial impetus behind Six Sigma, yet it is perhaps its status as a documented driver of superior financial performance that has led to its proliferation, subsequent diversification to design and lean environments, and dissemination across a number of application domains. In addition to traditional manufacturing applications of Lean and Six Sigma, significant gains in a number of "soft" or service application areas have been realized and include financial services (De Koning, Does, & Bisgaard, 2008), regional and national security (Edgeman, Bigio, & Ferleman, 2005), healthcare (Kaplan, Bisgaard, Truesdell, & Zetterholm, 2009) including surgery (Mason, Nicolay & Darzi, 2015), and energy production and distribution (Kaushik & Khanduja, 2009). In many of these latter applications, financial performance has been of secondary or tertiary importance and other considerations, such as ecological or societal sustainability has been deemed preeminent.

Table 1. DPMO values in relation to sigma levels

σ Level	DPMO When Perfectly Centered	DPMO With 1.5σ Displacement	Cost of Poorly Performing Process (CP ³)
2	46,000	308,537	Cost may exceed sales
3	2,700	66,807	25% to 40% of sales
4	60	6,210	15% to 25% of sales
5	0.6	233	5% to 15% of sales
6	0.002	3.4	< 1% of sales.

The key issue of “what is sigma?” remains. Symbolized by σ , the term ‘sigma’ is a measure of variation or “imperfection” widely recognizable as the standard deviation of process, product, or system output. Contextually, variation does not represent intentional introduced diversity, but is rather any departure from intended performance levels. *Higher* process sigma levels imply *lesser* standard deviation values so that higher sigma levels imply that a higher proportion of output or results will be associate with performance ranging from acceptable to superior. Higher sigma levels thus imply reduced ‘defect’ levels where a defect is anything not matching a required performance profile—for example—true Six Sigma is ordinarily associated with “near perfect performance” that is often cited as “3.4 defects per million opportunities for a defect”.

The method used to estimate a sigma level differs depending on whether quantitative or qualitative information is being assessed, but in either case captures the capability of the underlying process to deliver required results. Relative to prior discussion we find that ‘high sigma levels’ are associated with more capable processes. Defects per million opportunities for defects (DPMO) in relation to sigma levels and associated cost or loss due to imperfections are reported in Table 1, similar content of which may be found in a large number of sources, including Montgomery and Woodall (2008). DPMO values in Table 1 reflect an average process performance level displaced by 1.5σ from perfect centering. It is not always the case that a process should perform *within* limits,

since there are numerous reasonable circumstances where there is only an *upper* or *lower* acceptable performance limit. As revealed in Table 1, the commonly reported ‘3.4 DPMO for a true six sigma level process’ reflects displacement or a shift of 1.5σ from perfect centering, that is, from ideal performance level. Use of a 1.5σ displacement or drift factor – referred to in statistical parlance as a non-centrality factor – is based on the natural tendency of processes to vary through time within a range – that is, within ‘plus or minus’ distance of its (natural) average performance level, rather than ideal performance level).

Left alone, most processes tend not only to drift, but in fact have a tendency toward entropy or decaying performance so that process performance is often monitored and managed. There may be any number of motivations for improving performance, but it is this tendency toward entropy that necessitates the more mundane activity of monitoring and controlling a process at a stable level via tools such as failure modes and effects analysis (FMEA) or statistical process control charts (Montgomery, 2008; Shahin, 2004). Process monitoring and control ordinarily represents both pre- and post- Six Sigma project activity as does the associated use of continuous improvement practices such as use of the PDCA (Plan, Do, Study, Act) cycle that is central to kaizen and that is also known as the Deming cycle (Moen & Norman, 2010). Application of kaizen after breakthrough improvement has been attained via Six Sigma will generate ongoing incremental improvements.

Figure 1. Six Sigma COPIS $\Rightarrow$ SIPOC translation

SELECTED LEAN SIX SIGMA STRATEGIES AND APPROACHES

All Six Sigma strategies explicitly or implicitly have customer or, more generally, key stakeholder considerations at their core, including internal stakeholders. For that reason, both COPIS and SIPOC are central to most Six Sigma formulations. SIPOC is familiar as a generic business execution process whereas COPIS reflects how business should first be conceived before it is practiced. The letters are identical, but their flow reversed. COPIS indicates that the enterprise should first carefully elicit, elaborate, and assess customer (C) / stakeholder needs and desires that provide solid process output (O) indicators. These indicators then supply information concerning optimal configuration of processes (P) capable of delivering the outputs. Process configuration and requirements then influence inputs (I) and the suppliers (S) from whom inputs are obtained. This information is often used to construct a “COPIS

map” and to feed SIPOC practice. These concepts are illustrated in Figure 1.

All elements of the COPIS $\Rightarrow$ SIPOC translation chain are important, but clear and careful articulation and elaboration of customer / stakeholder needs is particularly so, since failure in this domain will almost certainly contribute to project failure. Generation and selection of poor concepts, or inadequate later deployment of strong concepts intended to fulfill customer needs will in like manner typically lead to project failure.

The most often used customer / stakeholder needs elaboration model is the Kano Customer Needs Model (Matzler & Hinterhuber, 1999) as portrayed in Figure 2. This model differentiates customer / stakeholder needs and wants into the self-explanatory categories of dissatisfiers, satisfiers, and excitors-delighters. Such needs may be further classified according to either service or product quality dimensions that include aesthetics, reliability, features, conformance, durability, serviceability, perceived quality, performance, responsiveness, competence, security, empathy,

Figure 2. Kano customer / stakeholder needs model

courtesy, access and communication (Golder, Mitra, & Moorman, 2012).

Included among increasingly important design and innovation considerations are biologically inspired biomimetic ones (Hartmann & Germain, 2015), and life-cycle / cradle-to-cradle / circular economy considerations (Bocken, 2016; Tempelman et al., 2015). In any case, the selected concept must ultimately be developed and deployed, with common deployment methods being QFD and axiomatic design (Rauch, Dallasega, & Matt, 2015). QFD matches customer / stakeholder needs or “what’s” to enterprise capabilities or “how’s” and then deploys those capabilities in order to yield the product, process, service or system and can

be adapted to accommodate changing priorities in customer needs (Asadabadi, 2016).

SIX SIGMA INNOVATION AND DESIGN

As previously noted, Lean Six Sigma Innovation projects customarily employ the DMAIC algorithm and Lean DFSS projects will ordinarily make use of the DMADV algorithm. These algorithms are described in brief in Tables 2 and 3.

Whether it is motivated by lean, innovation, or design considerations, a Six Sigma project is essentially always a team endeavor and as such

Table 2. Six sigma innovation DMAIC algorithm

DMAIC Phase		Description
D	Define	Define the problem and customer / stakeholder needs and requirements. Prepare project team charter.
M	Measure	Measure product, process or service defect rates and document constituent processes in their current incarnation.
A	Analyze	Analyze process data in order to set performance objectives, identify key sources of variability in terms of CTQs, and determine the overall current capability to fulfill those objectives.
I	Improve	Replace any environmentally or humanly damaging substances or actions with more environmentally or socially friendly alternatives.
C	Control	Rethink every product or service and functions thereof. Are they needed? Are they efficient? Are they ecologically and socially friendly?

Table 3. Design for Six sigma DMADV algorithm

DMADV Phase		Description
D	Define	The Define phase of DFSS aims to acquire and access the Voice of the Customer (VOC) and subsequently align goals for the product, process, service, or system with the VOC. Among VOC acquisition methods are use of focus groups; sample surveys; direct observation of customer use of similar product, processes or systems so that unspoken and more implicit information can be gathered; and examination of customer complaints. Goals should be so-called SMART (Specific, Measurable, Attainable, Relevant, and Time-bound) stretch goals – ones that are more likely to position the product, process, or service at the leading edge.
M	Measure	In the DFSS context measurement entails measuring and matching performance to customer requirements in order to quantify the VOC and align it with organizational and management goals.
A	Analyze	Analysis demands that the design of existing relevant products, processes, services or systems must be assessed to identify or determine suitability, performance, error or defect sources, and any corrective or innovative actions that may implemented. Among the many tools that may be useful in the Analyze phase are Design Failure Modes and Effects Analysis or DFMEA (Chen & Ko, 2009), concept generation and selection, and the Theory of Inventive Problem Solving or TRIZ (Ilevbare, Probert & Phaal, 2013).
D	Design	Design requires that the array of corrective or innovative actions identified in the analyze phase are embedded in the design and subsequent deployment of new processes required to concurrently activate the VOC and fulfill organizational and management goals. QFD, EVOP, and RSM are particularly valuable in this phase.
V	Verify	The objective of the verify phase is to assess performance of the design via such means as simulation, direct observation of the new design in its use environment but prior to marketplace deployment, or prototyping.

common to the Define phase is construction of, and agreement to a team charter that establishes purpose, goals, objectives, and code of conduct and engagement. While specific content of team charter may vary, elements that are typically included are an executive summary, projective objectives, project scope, the business case for the project, project organization, schedules, a communication plan, project control procedures, project assumptions, and a conflict resolution agreement. A key driver of the conflict resolution agreement specifically and the team charter more generally is to transform conflict discussions from that may otherwise be personality-driven into ones that are more issue-oriented. This discussion highlights the importance of good project management to conduct of any Six Sigma project. Similarly, all Six Sigma projects have a process orientation so that a value stream map (Gibbons, Kennedy, Burgess, & Godfrey, 2012) and one or more, more specific process maps are generally included.

Most Six Sigma projects will ultimately call for comparison of performance of an existing or conceived product, process or system to similar ones or to similar concepts so that some form of benchmarking (Watson, 2007) is typically re-

quired. In addition to previously cited ones, other often-used and widely familiar Six Sigma tools and methods span project management ones such as work breakdown structures and Gantt charts; ideation and creativity ones such as brainstorming, affinity diagrams, interrelationship digraphs, mind mapping, and storyboarding; and more analytically-based decision support ones such as the matrix diagrams, nominal group technique, theory of constraints / evaporating cloud (Sproull & Nelson, 2012), analytical hierarchy process, and SWOT (strengths, weaknesses, opportunities and threats) analysis.

Given the origin of the “ σ ” terminology it is unsurprising that various statistical and graphical methods ranging from simple to complex may also be brought to bear in Six Sigma projects. Among such tools and methods are Pareto charts, cause-and-effect diagrams, run charts, control charts, boxplots, hypothesis testing, designed experiments, and regression and correlation analysis with results that may be summarized by radar charts or displays such as performance dashboards.

While selected tools and techniques may generally prove more useful in one phase than another, a given tool or technique may be applied anywhere

useful in the DMAIC or DMADV structures. It is also true that two Six Sigma teams approaching the same issue may attack the issue differently and make use of differing tools and techniques and hence produce differing solutions. In any case and relative to constraints, a given team will endeavor to deliver as near to an ideal final result (IFR) as is possible. Numerous practical examples of both DMAIC and DMADV implementation can be found in the academic literature, with an especially rich resources being the journals *Total Quality Management and Business Excellence*, *International Journal of Lean Six Sigma*, *The TQM Journal*, and *International Journal of Six Sigma and Competitive Advantage*.

LEAN SIX SIGMA

Lean Six Sigma (LSS) derives from integration of lean enterprise methods that seek to reduce or eliminate waste with Six Sigma's quest for near perfect performance, hence LSS simultaneously seeks resource savings, cost savings, and value creation. Integration drives both the structure and content of specific LSS improvement efforts (Gremyr & Fouquet, 2012). LSS is a relatively new development with no uniform approach and literature that is immature relative to that for DMAIC and DMADV.

Many lean approaches derive from TPS (Ohno, 1988). TPS identifies multiple forms of waste (*muda*) that may be easily recalled via the acronym NOW TIME that represents non-quality (N), over-production (O), waiting (W), transportation (T), inventory (I), motion (M), and excess processing (E). Often non-value adding efforts in a process represent unnecessary waste. Womack and Jones (2003) add the manufacture of goods or supply of services that do not meet customer demands and expectations to the NOW TIME list of wastes that may also incorporate untapped or under-used human talent and creativity. Similarly, value stream mapping is helpful in pinpointing the

best place or places in a process where strategic change impacting CTQs can be executed.

FUTURE RESEARCH DIRECTIONS

A number of articles cited under "additional references" propose future research directions for Six Sigma directions. Since the DMAIC and DMADV algorithms follow well-established problem-solving approaches, the most obvious future research directions for Six Sigma are ones that will be associated with new applications areas, and adaptation of tools and techniques from other fields, many of which are suggested by Edgeman and Dugan (2008). In particular, environmental deterioration and pressing societal needs are areas where radical improvement needs abound and hence where application of Six Sigma Innovation, Design, and Lean strategies and methods should be carefully, yet urgently explored (Kumar, Kumar & Haleem, 2015).

Many projects combine significant innovation with new design so that development of one or DMAIC-DMADV hybrids can be anticipated. Similarly, it can be expected that effort will be dedicated to development of standardized or semi-standardized mixtures of Lean and Six Sigma methods to produce a LSS algorithm akin to DMAIC and DMADV. Such future directions are relatively predictable.

Less predictable is the issue of how Lean Six Sigma will probe and expand the "big data frontier" that is commonly viewed as critical to advancing innovation, competition, and productivity (Dubey et al., 2016). In large the question is one of how Six Sigma will morph to incorporate both the challenges and advantages of computationally intensive methods in order to effectively and efficiently leverage massive amounts of information and disparate sources of enterprise, social, and competitive intelligence. That such transformation will occur is almost certain and is also likely to spur refinement or significant innovation of such Six

Sigma tools and techniques that address customer or stakeholder needs elaboration, assessment and deployment.

CONCLUSION

Whether applied in innovation, design, or lean contexts, Six Sigma aims to deliver superior value through superior performance of products, processes or systems that are of critical importance to key enterprise stakeholders. Discussed herein have been the means by which this accomplished.

Use of Six Sigma has proliferated due in large to significant documented contributions to the financial bottom lines of numerous enterprises. While superior financial performance often provides the initial impetus behind Six Sigma adaptation, it must be emphasized that financial performance generally follows significant enhancement of products, processes or systems specific to enterprise context that may be as disparate as surgical procedures, harvesting methods, service delivery, a new manufacturing process, or related to safety and security.

KEY TERMS AND DEFINITIONS

Critical to Quality (CTQ) Characteristics:

Traits or factors that are critical to fulfillment of customer or other stakeholder needs. These are key levers in the delivery of value through process, product, system or enterprise designs or innovations.

DMADV: Define – Measure – Analyze – Design – Verify is an algorithm or approach associated with Six Sigma and Lean Six Sigma that is commonly used in process, product or system design applications.

DMAIC: Define – Measure – Analyze – Improve – Control is an algorithm or approach used in Six Sigma and Lean Six Sigma projects that are aimed at significant innovation in and improvement of existing processes, products or systems.

Kano Customer Needs Model: A model that differentiated customer and other stakeholder needs into three primary categories: those that dissatisfy customers, customer satisfiers, and those that excite customers. Specific knowledge of these needs is used to inform product, process, or system innovation and design.

Lean Six Sigma: Highly structured innovation, design, and lean enterprise strategies and methods for acquiring, assessing, and activating customer, competitor, and enterprise intelligence in order to deliver superior product, process, system, or enterprise performance that benefits all relevant stakeholders through best and next best practices and sources of sustainable competitive advantage.

Quality Function Deployment (QFD): A meticulously detailed method of mapping and subsequently executing enterprise capabilities and resources to customer and other stakeholder needs. QFD is often practiced as a four-stage process that carries and implements the voice of the customer from concept to market.

Value Stream/Value Chain: A value stream is a sequence of activities needed to design, produce and provide a specific service and along which information, material and value flow. A value chain is a set of linked activities that transform inputs into outputs that in turn add to at least one of the ecological, societal or economic bottom lines and help create competitive advantages. Linked to Six Sigma and Lean methodologies the goal is to create sustainable competitive advantages.

Motivational Factors of Telework

Arlene J. Nicholas

Salve Regina University, USA

INTRODUCTION

This chapter discusses telework as a motivational option for workers and employers. Telework can be performed as a supplemental or a full-time employment opportunity for local, regional or global work. Teleworkers must be self-starters, able to work with minimal supervision, and, in some cases, rely on technological communications for professional interactions. Teleworkers can enjoy flexibility for work and personal responsibilities (Greer & Payne, 2014) while organizations can gain more satisfied productive employees (Bloom, 2014; Caillier, 2014). An overview of telework's motivational benefits, incentives, and organizational examples for both employees and management are identified.

BACKGROUND

Telework is a growing method of employment with a variety of benefits. Telework enables work from anywhere, anytime through information commu-

nication technologies (ICT) (Garett & Danziger, 2006). A recent Gallup poll of 1011 adults in the U.S. shows a steady increase in telework, with a short term dip caused by the 2008 economic crash (see Figure 1) (Jones, 2015).

Forbes analyzed 40,000 jobs posted on Flexjobs 2015 to create the Top 100 Companies for Remote Jobs list (See Appendix A). The 36% increase of listings from the previous year included jobs in IT, medical and health, sales, administration, customer service, education and training, and marketing (Shin, 2016). The variation of jobs permitting telework include full time, part time, contract and seasonal workers. Unexpected were some positions, such as Director of Community Advancement - full time, Physiotherapist - part time, Expert Wellness Coach - part time, and Vice President of Communications and Development - full time (FlexJobs, 2016). Other recently posted positions are listed in Table 1.

Many jobs can be a fit for telework which is considered one of those best practices that allows employees flexible options for improved work/life balance. For organizations, telework is a savvy

Figure 1. Increase of teleworking

strategic management plan (Kowalski & Swanson, 2005). Telework brings increased benefits to both the employer and the employee (see Table 2).

TELEWORKERS

The number of teleworkers is growing in most sectors every year. A breakdown of organizations using telework was done by GlobalWorkplace-Analytics (2016) based on data from 2005 to 2014 of U.S. telework population. In those nine years, except for occasional small drops in government workers, such as 2013 which rebounded in 2014, all other organizations experienced growth. Table 3 depicts the figures from 2012 – 2014.

According to the Telework Advisory Group of World at Work, the representative teleworker is a college educated 40 year old male working from home. And although this credible not for

profit organization of 30,000 members in 100 countries, founded in 1995, reported that people who worked remotely one day a month declined, the number working more than one day a month increased (Telework 2011, 2011). Teleworkers often include knowledge workers, a term coined by management author Peter Drucker, who are occupied with analysis and manipulation of data as opposed to production (Knowledge worker, 2010). Today's technology has enabled knowledge workers to work remotely from anywhere in the world be it at home, an offsite office or telecenter, or even a coffee shop. Improved ICT, personal incentives and even employer encouragement will add to the number of teleworkers.

Legislation

In March of 2010, a House subcommittee approved legislation to promote telework in Federal

Table 2. Telework benefits

Organizational	Employee	Societal
Productivity	Savings	Work opportunities
Retention/attraction	Flexibility	disabled, homebound, distant
Virtual Workplace	Work/life Balance	Ecological – less car pollution
24 hour cycle	Some autonomy	Environmental
Continuity	Job satisfaction	less traffic congestion

(Caillier, 2014; GII, 2008; Rhodes, 2009; Telework=better, 2009; Ursery, 2003)

Table 3. Teleworkers by type of employer

Employer	2012	2013	2014
For Profit	2,501,855	2,689,963	2,860,517
Non Profit	314,984	355,327	355,327
Local Government	119,622	122,530	131,597
State Government	164,382	160,661	170,932
Federal Government	157,682	144,966	158,688
Total	3,268,525	3,480,447	3,677,061

Source: GlobalWorkplaceAnalytics

agencies. The Telework Enhancement Act of 2010 (<http://www.gpo.gov/fdsys/pkg/BILLS-111hr1722enr/pdf/BILLS-111hr1722enr.pdf>) mandated a government-wide telework policy. Agencies are required to allow eligible employees to work at least 20 hours a week remotely (Rosenberg, 2010).

The law has been successful. In 2009, only 10% of eligible federal workers telecommuted. In Sept 2011, almost 21% were regular teleworkers (Resneck, 2012). It increased in 2012 to 24% and again in 2013 to 27% (2014 Status of Telework, 2014). However, there are still many federal employees who are eligible to telework but are not participating. Some concerns are double-taxation costs for the worker in both their home state and work state (Allen, Golden & Shockley, 2015). The Multi-State Worker Tax Fairness Act of 2014 that would reduce tax burdens for employees and their payroll departments has been under ‘committee consideration’ since March of 2014 (H.R.4085, 2014). Passage of this bill could raise the numbers of federal and private sector teleworkers.

Many states have their own statutes or executive orders and some simply have policies to motivate telework options for state-agency employees. A growing number of states have tax incentives on percentages of teleworkers or conversion costs for agencies (Allen, Golden & Shockley, 2015).

Another useful part of the Telework Enhancement Act legislation is the requirement for agencies to train managers on properly supervising teleworkers (Rosenberg, 2010), this is something the corporate world must address also (“Managing

teleworkers ...”, 2009). Training managers how to supervise and guide teleworkers may be challenging given some resistance noted by earlier and recent studies of managers unwilling to give up direct control of the visible worker (Clear & Dickson, 2005; Daniels, Lamond, & Standon, 2001; Tuutti, 2012).

Motivation

Beyond legislation, adoption and implementation of telework programs can have a positive effect on job satisfaction (Bae & Kim, 2016). This satisfaction can be a very motivating factor in choosing a position with teleworking as pay and titles are not always the determining factors (Gose, 2013). There can be reduced turnover intention when telework is an option (Bae & Kim, 2016). This attrition factor combined with higher levels of performance, satisfaction and creativity (Vega, Anderson & Kaplan, 2015), should motivate managers to implement telework.

If managers deny teleworking requests, it could result in de-motivating workers. In a study of Department of Health and Human Services workers (98% of whom are eligible for telework), the employees who were denied the opportunity to telework reported lower motivation than the employees who did telework (Caillier, 2012). Interestingly, employees who teleworked frequently, more than two days a week, reported less motivation than employees who teleworked infrequently, up to two days a week. According to Golden (2006), this decline of satisfaction with

extensive telework is a result of isolation from co-workers and lack of face-to-face interaction with managers. Hybrid work arrangements of office and telework can offer both face-to-face and flexible options (Sewell & Taskin, 2015).

A positive aspect of being away from the workplace is avoiding office politics and gossip (Ellison, 2004; Fonner & Roloff, 2010; Kurland & Cooper, 2002). Physical distance can ensure contact, such as phone or e-mail, is focused on job related matters, not drama. Of course, avoiding this type of information sharing or wanting to shop talk is a personal characteristic of the employee.

As noted earlier, employees could be motivated by savings that can include gas, car wear and tear, clothing, child/elder or even pet care arrangements; flexibility for care arrangements, doctors' appointments, and other chores or business needs; autonomy to meet business/home needs; and contributing to green environmental effects (Caillier, 2012; Caillier, 2014; GII, 2008; Rhodes, 2009; Telework=better, 2009; Urserly, 2003).

Challenge to Management

Managers of teleworkers must motivate and inspire out of sight workers and provide authentic information sharing, from managers to workers and between work teams. An affinity distance problem can result when there are trust issues between team members who have never met one another (Reilly & Lojeski, 2009). Some non-teleworkers can have resentment of teleworkers and perceive doing some of the teleworkers' duties (Greer & Payne, 2014).

Managers too must overcome lack of trust for workers who are miles away (Brown, Smith, Arduengo & Tayolor, 2016; Leonard, 2011). When Marissa Meyer was brought in as CEO to revitalize Yahoo, she stopped the telecommuting program (Cohan, 2013; Gaudreau, 2013). CEO Hubert Joly of Best Buy halted the Results Only Work Environment (ROWE) program a week later, also as a revamping scheme. Both moves, and others, were attributed to a weak job market

that gave management tighter controls as these eliminations countered studies of increased productivity, retention and job satisfaction (Cohan, 2013; Gaudreau, 2013; Valcour, 2013).

In a study by Sewell and Taskin (2015) of 31 information technology and research and development teleworkers, 26 teleworked one day a week and 5 teleworked two days a week. The teleworkers perceived more intense supervision and direction, even of tasks that would have been under their authority if still in the office. Technology and customer service has to be combined with human resource management for a productive teleworking program (Blount, 2015).

Management has to have a balance of monitoring while encouraging open communications among teleworkers, site workers and management. This is definitely a challenge and relatively new to many managers. Just as there should be guidelines for teleworkers, more managers should get training. If little more than 17% of organizations with some kind of flexible work program provide training for managers of flexible workers (Sharp, 2013), there is considerable room for improvement.

Today's Workforce Considerations

Premiere Global Services Incorporate surveyed 3,000 knowledge workers in North America (NA), Europe, the Middle East and Africa (EMEA) and Asia Pacific Japan (APJ). Of those surveyed, 79% reported that they teleworked and 54% were without any policies. NA reported the widest use of telework followed by EMEA and APJ (2015 PGi Global, 2016).

Some attribute the rise to 37% teleworkers in the U.S. to the winter of 2014-2015 and record-breaking cold and snow for the Midwest and the Northeast (when snowstorms even had names like 'Juno' in January 2015). Businesses continued to do productive work through telework (Plumb, 2015).

Earlier reports had lower percentage of teleworkers at 9%, the same as Europe, compared to emerging markets: Asia-Pacific, 24%; Latin

America, 25%; Africa and the Middle East, 27% each. The highest percentage reported is India with 82% teleworking at least once a week, and 57% are frequent teleworkers, some of which is outsourced jobs (Reaney, 2012).

Some differences certainly relate to job opportunities and cultural norms. Studies of U.S. workers note the social isolation or relational impoverishment of teleworking has negative effects on job performance (Gajendran & Harrison, 2007; Golden, Veiga, & Dino, 2008). But the workforce of today is composed of many generations and what Baby Boomers (born 1946-1964) may perceive as detrimental to their careers, such as being away from the workplace, could appeal to Gen Xers (1965-1980) with families and to the Net Generation's (1981-2001) tech comfort.

For example, teleworkers have reported many benefits that could relate to a new generation of workers who are said to be "less at home with the real world than in the virtual world" (Eisner, 2005, p.2). Combining that technological penchant with the Net Generation's team-orientation (Bridges & Johnson, 2006) would seem to make the virtual team scenario of telework very compatible and its eco-friendly aspect would appeal to these socially conscious citizens (Eisner, 2005; Raines, 2002). Many Baby Boomers have been assessed as reluctant to use new technology which has not really been designed for or marketed to older users (Burdick, 2005). There may be need for additional training and support for those older workers.

SOLUTIONS AND RECOMMENDATIONS

For teleworkers who are beyond the reach of the office, if there is one, interaction with managers and team members can be critical. Managers need defined meeting times and agendas, and, in the cultural context, learn to communicate in the language of the workforce (Klein, 2008). Infrequent teleworkers, especially those who may be part of an alternate shared workspace arrangement, such

as in-office work on Monday/Wednesday/ Friday with the same office used on Tuesday/Thursday by another colleague, should also be connected by management arrangement meetings.

Peter Linkow, president of WFD Consulting, based in Newton, MA, and research leader of the Conference Board's Research Working Group on Managing a Distant Workforce gives 10 recommended guidelines for distant managers:

1. Recruit for character, build fundamentals then develop distance competencies.
2. Emphasize relationships as much as tasks.
3. Create intra-company collaboration, then assess it.
4. Build solid communication infrastructure.
5. Secure the upper management support that employees need to be successful.
6. Set clear goals and then empower distant employees to determine how to achieve them.
7. Focus managers on creating a work environment that enables employee achievement.
8. Concentrate on the job environment.
9. Approach cultural differences with an open mind.
10. Support the distant managers who report to you. (Klein, 2008)

Selection of the right workers for telework as well as setting detailed and specific goals is critical (Wilkie, 2015). Making employees successful will also depend on easy to use technology and readily available support. The older workforce is not as resistant to technology as it is disappointed with its user unfriendliness which limits their use of information communications technology (ICT) (de Koning & Gelderblom, 2006). The younger workforce will demand speed and mobile applications (Tapscott, 2009).

Training for teleworkers should include using technology to accommodate work and communications, creating separations between work and non-work roles and "planning appropriate tasks to maximize daily productivity" (Greer & Payne, 2014, p. 107). Some face-to-face interventions

are recommended, but when that is not always possible, video conference, Skype, Facebook, personal blogs and even Second Life virtual meetings have been used to give some connection between teams and leaders (Klein, 2008). Reiterating the mission/vision/goals can help reduce operational distances amongst teams' interpretations of the organizational practices (Reilly & Lojeski, 2009). Results based managers will get the best out of their employees whether they are in the office or miles away (Leonard, 2011).

FUTURE RESEARCH DIRECTIONS

The value of teleworking programs to organizations and workers must continually be assessed. Before and after comparisons of the effects of telework programs should be analyzed. Are there differences in desirability according to gender, age, distance from work, family composition, culture? Organizations will want to know retention, recruitment, job satisfaction and productivity based on telework options. Are there technology pitfalls to be avoided? Concern for secure data transmissions, customer/client/patient confidentiality, bandwidth capabilities, support and back-up plans could determine what organizations will envision as a cost/benefit investment in telework.

Further studies on the reported curvilinear relationship of telework time for increased satisfaction with limited hours/days and then a decrease of satisfaction with too many hours/days (Golden & Viega, 2005) should be conducted. This could be a critical phenomenon to understand for organizations that can offer varied schedules of telework.

CONCLUSION

Telework already is an indispensable option of working for the myriad benefits reviewed. These include continuity of work functions, attracting and recruiting employees, office space savings, and global extensions for organizations; flexibility,

work/life balance, clothes/transportation savings, family care ability for employees; reduced traffic, less emissions, cultural and disability options for society. The difficulties for management of selection, training, security, procedures and connectivity to workers must be met as well as keeping up with the quick pace of changing technology. Clear and open communications can motivate and maintain a thriving workforce from anywhere, at anytime. The organization, managers and employees need to work in a trusting cohesive method to develop a productive teleworking experience (Brown, Smith, Arduenga, & Taylor, 2016).

KEY TERMS AND DEFINITIONS

Affinity Distance: Emotional separation between virtual team members who have no personal relationship.

ICT: Information communications technology.

Knowledge Worker: Researchers, planners, analysts and/or developers who acquire, manipulate, and analyze information.

Operational Distance: Psychological gaps regarding workplace issues.

Physical Distance: Variances in space, time and environment.

Telework: Work done remotely from the office using some form of telecommunications; also referred to as telecommuting.

Virtual Distance: Working and communicating mainly, or exclusively, through technology.

Organizational Transparency

Gustavo de Oliveira Almeida

Federal University of the State of Rio de Janeiro, Brazil

Claudia Cappelli

Federal University of the State of Rio de Janeiro, Brazil

Cristiano Maciel

Federal University of Mato Grosso, Brazil

INTRODUCTION

Transparency is one of the most frequent words in the contemporary public discourse, due to the growing demand for organizational transparency from the many stakeholders, which include shareholders, national and international watchdog organizations, the mass media and influential bloggers (Wehmeier & Razz, 2012). For instance, since shareholders invest money in corporations, they require financial disclosure, the exposure of future strategies and the revealing of the corporations' decision-making processes. Also, factors such the crisis in the 'new markets' and financial crisis have increased international and national watchdog organizations such as Transparency International to continue to raise the issue of corporate transparency (Wehmeier & Razz, 2012).

Although the notion is frequently part of the daily discourse, the concept of transparency is rarely defined – neither in the news nor in the companies – beyond common-sense understandings as 'openness', 'insight' or 'clarity' (Christensen & Cornelissen, 2015).

According to Hood (2006 apud Wehmeier & Razz, 2012) the roots of transparency were present in ancient China and Greece. The Online Etymological Dictionary (2007), points out that the term transparency is derived from the word "transparentem", meaning "show light through", which in figurative use became "easily seen through", its figurative meaning started being used

somewhere between the XV and XVI century. The word continued to be used throughout and became part of many Latin derived languages such as the Italian, Spanish, Portuguese, French and English (Vaccaro & Madsen, 2009).

Transparency is usually presented as an unquestionably positive concept for the public, governments, and firms, found in almost every code of conduct, held as a foundational principle and an objective of most governmental and non-governmental organizations. However, fewer authors dedicate their research to present the issues or negative consequences of transparency (Fenster, 2006). There is an established view that transparent companies, governments, institutions and processes are essential to achieve corporate social responsibility, social justice, environmental security, true democracy and wellbeing (Menéndez-Viso, 2009). In the words of Christensen & Cornelissen (2015), this veneration of transparency as a value is the "myth of transparency". More than that, the contemporary organizations are in the business of transparency, as the result of legal, social or public pressure, or even as a self-goal to be transparent. Nevertheless, although the transparency is a growing concern, it does not mean that they are open about everything they do (Christensen & Cornelissen, 2015)

Thus, in a context dominated by frequent episodes of corporate wrongdoing, transparency is often presented as a remedy for the trust issues between the organization and its stakeholders.

Some studies have consistently pointed out the role of transparency in creating, maintaining, or repairing trust, between organizations and stakeholders (Schnackenberg, & Tomlinson, 2014). Consequently, many companies have embraced the concept of transparency believing it would bring increased levels of trust among the public, more specifically shareholders or investors, and other actors such as consumers, government and regulators (Williams, 2005). As a result, in a search for a more precise definition of transparency, Schnackenberg & Tomlinson (2014) nominated three factors, which the authors define as theoretically viable and managerially relevant: disclosure, clarity, and accuracy. The first factor disclosure increases as stakeholders perceive information as more relevant and timely; while clarity is related to the stakeholders' perception of the information as understandable; and finally the factor accuracy is defined as a perception by the stakeholders that the information is reliable. Each of these dimensions contributes in a singular way to the transparency by increasing stakeholder confidence in the quality of information received.

Rosendorff and Vreelandde (2006) define transparency as the dissemination of regular and accurate information. According to Leite et. al. (2010), there are three different levels of transparency: social transparency, target transparency and organizational transparency. According to Fung (2007), social transparency allows citizens to be more informed and encourages the disclosure of information as a regulation mechanism of centers of authority, while target transparency aims to reduce specific risks or performance problems through selective disclosure by corporations and other organizations. The concept of organizational transparency is defined as the disclosure of organizational information between an organization and its stakeholders, allowing to the society to verify whether the organization's activities are consistent with regard to the society's interests (Cappelli, 2009).

Describing in more detail the concept of organizational transparency, it is composed of five

dimensions: access, usability, informativeness, understandability and auditability. All of them can be applied for information transparency and business processes transparency (Cappelli, 2009). The information transparency is the feature related to the information of interest, and its ease of access, ease of use, quality of content, understanding and auditing. In turn, process transparency is the feature that enables the citizen access, easily use, understand and audit the processes dealing with information of interest. Process transparency requires that the transformation steps of the process be transparent, that is, it should be possible to understand its enactment (Cappelli, 2009).

This chapter has as its main objective to present and detail the concept of organizational transparency, and its dimensions, according to a review of literature. The chapter also aims to contrast the importance and implications of transparency for the society and organizations and to present research agenda in the topic.

BACKGROUND

Although transparency is not a recent concept, it remained a secondary concept until the end of 20th century, and an increased interest in transparency has emerged in organizational research only in the past two decades, mostly due to the corporate scandals in that period (Schnackenberg & Tomlinson, 2014). In addition, diverse areas of research have studied different aspects of transparency.

Generally, information systems researchers investigated the role of transparency in the relation of business to consumer relationships and digital markets. Meanwhile, organizational behavior researchers studied transparency in the context of organizational trust development, organizational identity, perceptions of leadership, and organizational culture, while researchers of finance and accounting have examined transparency in the context of financial markets, corporate disclosures, and monetary policy decision making, among other areas (Schnackenberg & Tomlinson, 2014).

Moreover, various social actors and institutions defend the value and significance of transparency without agreeing on what it means and encompass. Even though not precisely defined, transparency is treated as a way to improve trust in organizations and to legitimate the organization's acts without any form of questioning (Christensen & Cornelissen, 2015).

Henriques (2007) examines different constituents of transparency as a concept and frames them in the context of organizations, claiming that transparency will be essential for successful organizations. Therefore, transparency has obtained a status in contemporary society much like dogma or religious principles, or "myths" (Christensen & Cornelissen, 2015). Myths are not simply false understandings or accounts; instead, they are descriptions of the world presented in a narrative form with the objective of producing meaning and direction for a community and its members (Midgley, 2004).

Holzner and Holzner (2006 *apud* Cappelli, 2009) present social and historical perspectives to understand the forerunners to open government movement, in which transparency is key towards more open and democratic societies. However, a central issue facing any implementation of Information and Communication Technologies (ICT) is their relationship to individual and shared values and conceptions of the good, making it necessary determine what is acceptable and unacceptable regarding the uses of technology. In this discussion is important to understand the reasons regarding the creation of transparency and the preservation and promotion of the interests of all of organizational stakeholders. It is imperative to note that corporations are getting increasingly dependent on ICT, due to the fact that organizational process tend to be heavily related to collection, organization, storage, and communication of information. Nevertheless, although the new ICT technologies enable transparency it does not drive the implementation of transparency.

Schnackenberg & Tomlinson (2014) compiled a series of four common features of the different

definitions of transparency. The first feature is that transparency is about information. Most research present transparency as a critical element of knowledge sharing, and highlight that the augment of transparency is connected to an increase in awareness, coherence, and comprehensibility to information exchanged between two parties. Other finding is that most definitions of transparency share the notion that transparency relies on intentionally shared information, performed in a systematic way. The third common feature suggests that transparency is a perception of received information. Finally, Schnackenberg & Tomlinson (2014) have found that transparency perceptions vary according to the perceived quality of information. This fourth feature was associated with the importance of information quality, which was present in an obvious or implied manner in almost all of the reviewed studies.

Schnackenberg & Tomlinson (2014) declare that there is a lack of theoretically grounded consensus on the transparency construct, what they call a "patchwork" of various operationalization from many areas of academic inquiry. The mentioned authors also state that the present literature on transparency does not suggest a definite solution on how the construct should be conceptualized.

Similarly, the current empirical studies on transparency have suffered from a great deal of conceptual variation, also disagreeing on what is meant by information quality. Thus, the operationalization of the transparency construct vary significantly and include concepts such amplified disclosure of information, greater openness and accuracy of information, higher visibility and accessibility of information, increased clarity and understandability of information, reduction on the concealment of information, and better timing of information disclosure. Thus, although there is a great deal of research an interest on transparency, a consensus has not been reached concerning which factors discriminate between high and low quality information. Still according to Schnackenberg & Tomlinson (2014) this lack of convergence of a single explanation of the aspects of information

Figure 1. Transparency SIG

Source: Cappelli, 2009

quality more relevant to transparency has hindered researchers from advancing a systematic theory of antecedents and consequences of transparency.

According to Cappelli (2009), transparency is a concept related to information disclosure, employed in different settings, mostly related to the empowering of citizens with regard to their rights. The issues of transparency are directly linked to information processing or information technology. Cappelli (2009) mapped these contexts into an “SIG” chart (Figure 1) to characterize the elements that contribute and are necessary to reach transparency:

Although most of the literature focuses on information transparency, Weber (2008) discusses the dimension of process transparency. A further analysis of the transparency concept indicates that the processes that produce information should themselves be transparent. According to Cappelli et. al, (2007), the transparency of the organizational process is related to the existence of organizational policies that aim to present to the stakeholders information about the organiza-

tion according to general aspects of access, use, presentation, understandability and auditability.

According to a literature review performed by Schnackenberg & Tomlinson (2014), researchers have conceptualized transparency in three primary ways: disclosure, clarity, and accuracy. Their findings have found that disclosure is usually defined as the perception that relevant information is received in a timely manner, in this regard, many studies present the disclosure as a central dimension of transparency.

The concept of disclosure implies that information must be openly shared for it to be considered transparent. On the other hand, clarity is defined as being the perceived level of lucidity and comprehensibility of information received from a sender. It is important to note that disclosed information consisting of industry jargon, unknown foreign languages, and complicated mathematical algorithms are not transparent even if it is thoroughly disclosed. That is, the transparency is not present if data is available but not understandable to the receiver. Finally, the concept of accuracy is

Figure 2. Three proprieties of transparency

Source: Schnackenberg & Tomlinson, 2014

related to the perception that information is correct to the extent possible given the relationship between the parts. In addition, information cannot be transparent if it is purposefully biased or false. However, accuracy does not mean that information must be completely correct for it to be considered transparent (Schnackenberg & Tomlinson, 2014)

Instead, accuracy suggests that material claims should reflect precise qualifications about their expected validity for information to be deemed transparent. Accuracy has some differences from disclosure and clarity since it deals with information reliability rather than completeness or understandability. Figure 2 has the three components of transparency along with their brief definition:

Information Systems and Organizational Transparency

The emergency of new ICTs is an important force that is driving organizations to higher degrees of transparency. The new technology can transform opaque organizations into transparent ones, allowing the stakeholders of institutions to have full accessibility of information regarding issues that affect their interests (Vaccaro & Madsen, 2009). More than that, transparency is a new ethical virtue of organizations, which is shaping and revolutionizing business practice, turning into a required feature for gaining and maintaining customer trust and to establish collaborative relationships with

all stakeholders, and it is heavily based on ICT, which has progressively increased role.

Consequently, technology is a key factor to promote transparency, but organizations may only implement ICTs that provide competitive advantage, *in lieu* of systems and processes created to promote transparency, unless the organization notices advantages on using IT differently than in their core business activities. In addition, while ICTs do allow higher access corporate information than ever before, they can also be employed to limit hierarchy and control of the information (Elia, 2009). Thus, to be transparent an organization needs to produce information, enabled by processes based on information technologies (Menéndez-Viso, 2009). According to the author, this portrays some issues with the transparency:

- It needs an active production of information opposed to a passive disclosure of data. The data has to be produced and made transparent (by having the proprieties of transparency: complete, understandable and reliable)
- The transparency of an organization is related to the required information as demanded by the various stakeholders
- The level of transparency can be measured with instruments analogous to the types used in quality control

- It is not free, it has some associated costs related to a organizational structure/ systems
- There is an economy of scale on the “transparency”, that is, bigger organizations or governments are abler to produce and publicize their information

According to Bertot et al. (2010), transparency and the right to access government information is now internationally regarded as essential to democratic participation, trust in government, prevention of corruption, informed decision-making, accuracy of government information, and provision of information to the public, companies, and journalists, among other essential functions in society.

Transparency in governmental relations is so important that it was the topic of the first memorandum signed by Barack Obama on his first term (Obama, 2009). According to the memorandum transparency “promotes accountability and provides information for citizens”. In addition, the document points out that the lack of transparency makes impossible to monitor the acts of companies, governments, and other organizations, and in turn, they would be less prone to act fairly. The document states that transparency promotes accountability and inform citizens about government actions, and calls for U.S Federal Agencies to employ new technologies to divulge information about their decisions in an online and prompt manner, ideally using the feedback of the users to identify what information is of greater interest (Obama, 2009). Still, many authors also point out the limitations of transparency.

According to Fenster (2006), governmental transparency cannot be complete, since complete access to all governmental data is not a conceivable scenario for governments. This inability comes in part from prohibitive logistical issues and costs, but also, this kind of disclosure would prevent the correct functioning of many of the government’s most important operations. Other issue is that full transparency is a threat on the

privacy of citizens, who are usually obliged to give most of their personal information to the government. Fenster (2006) also states that the excessive disclosure of information may render a nation more susceptible to security breaches and less able to enforce its own laws because evildoers will have greater access to information that could be used to threaten the health and safety of the public. Christensen & Cornelissen (2015) insist that being transparent is usually taken as a promise of openness, exposure and insight and access to the truth about the organization, the commitment to organizational transparency is based on the principle that if procedures and methods are open to scrutiny, then the organization is open to critique and ultimately to improvement. Thus, transparency is seen as a reply to the demand for increased openness and accessibility, and counting on that openness facilitates insight and clarity, organizations increasingly adopt their structures to signal a practice of openness and truthfulness.

It is worth emphasizing that the technological tools must provide citizens with easy and rapid interaction, enabling the public to contribute to the definition of how public resources are applied. Anjos and Ezequiel (2011) show that the use of new technologies by public administration may represent an openness of the governments to the public, allowing ample access to the digitalized databases. The right to use these databases to obtain information and services directly, without intermediaries, is an important contribution to exercise of citizenship. Consequently, the use of technology can contribute positively to the dissemination and guidance given to citizens, if methods to improve the usability are implemented, allowing the use of the information by citizens.

Nielsen and Loranger (2007) present usability as a quality attribute related to the easiness of using something. More specifically, usability refers to the quickness with which users can learn to use something, their efficiency in using them, how much they remember of it, and how much the users like to use it. Therefore, web information systems expected to be transparent have to provide

ease of use, clarity and comprehensibility of the information available.

Accordingly, the use of ICTs as a mean to transparency, and the central role of the organizational intention on the implementation of technology make clear how the right to know (information) is not automatically granted when using ICTs. On the contrary, the use of ICTs should be guided by a theory of disclosure and its relationship to organizational and stakeholder interests, and to design systems that have high degrees of usability, as to allow the broad use and understandability of the information provided. At the same time, currently there is small attention to the rights to know of the stakeholders (Elia, 2009).

SOLUTIONS AND RECOMMENDATIONS

It is noteworthy that the level of disclosure, or transparency, can be managed by the organization. The organization can diminish its level of disclosure by making more information secret; or it can increase disclosure by the employing open information systems. There is a strong research evidence that managers have a tendency to conceal negative organizational information. In addition, organizations can profit from not disclosing proprietary knowledge. Still, according to empirical studies organizations may keep two kinds of secrets: sanctioned and unsanctioned secrets (Schnackenberg, Tomlinson, 2014).

The sanctioned secrets are those that are intentionally hidden by the organization for the purposes of competitive advantage, they are “sanctioned” because keeping this kind of information secret is commonly considered as a legitimate action by the stakeholders. Fung et al. (2007) use the concept of target transparency as a way for organizations to reduce specific risks or performance problems through selective disclosure and does this by providing a careful analysis of the constituents of transparency. On the other hand, the stakeholders see the unsanctioned secrets as illegitimate, even

though these secrets may have resulted from the need to maintain competitiveness or good image during internal organizational crises (Schnackenberg, Tomlinson, 2014).

According to Christensen & Cornelissen (2015), in the last years, transparency has developed from a question of how organizations can adapt to external requests for information to a deliberate strategy used to pursue respectability and social accreditation through the perception of being more transparent. Business consultants are recommending to organizations when dealing with the call for transparency to be proactive in carefully choosing the fields and the activities where they will demonstrate this value to their stakeholders. This notion of commitment beyond compliance, that is, disclosing more than obliged to, is being recognized as social responsibility, where corporations increasingly are expected to move from agreement to engagement. Both trends brings the necessity of proactive organizational initiatives in the transparency field (Christensen & Cornelissen, 2015).

Oliveira and Maciel (2013) assert that public spending transparency is an essential factor for strengthening the relationship between society and public managers. The disseminated information must be clear, understandable and easy to access. The citizens’ access to simple and understandable information is the starting point for greater transparency. It is important to notice that since being transparent is an active instead of a passive act, organizations carefully select, simplify and summarize data before they are revealed, they selectively disclose information, in their own timing of disclosure, which sometimes can be used to avoid critique or deal with potential issues (Oliveira & Maciel, 2013).

It can be argued however that transparency not only incorporates the rather passive right of every citizen to have access to information, but also the much broader and more pro-active duty of the administration itself to ensure that information about its policy and actions is provided in an accessible fashion (Curtin et al., 2006). Moreover,

the stimulus to public transparency must be one of Public Administration goals, since it contributes to strengthening of democracy.

FUTURE RESEARCH DIRECTIONS

The importance of transparency has been long debated and it is acknowledged by both academia and general public, or in Christensen & Cornelissen (2015) words it is already a “myth”, a characteristic highly coveted by organizations, government and society, even though there is a general lack of understanding of its complex nature, costs and real possibilities. In this regard, Fenster (2006) highlight the negative side of transparency, which need to be more deeply understood. The costs associated with a greater disclosure and the needed limits and limitations of the transparency need to be further considered by the field as a whole.

The process of transparency has turned into a discourse of corporations, which already use it as a strategy of disclosing information that they deem favorable, while keeping their “secrets” or making it less understandable through obscure reporting, hard to find data and excessive use of jargon. Therefore, new research ought to be more critical of transparency. Not that the new research should not advocate for the disclosure of understandable, complete and reliable information. Instead, new research should disclose the true nature of transparency and the organization’s attitude towards this new trend, including a better consideration of the benefits and costs of transparency.

New research should focus on a general operationalization of transparency construct, if it is feasible. Future research might find that the concept is dependent on industry, type of stakeholder of other variable. Other important source of research on transparency is related to Open Government Data¹, which calls for open data and easy access to previously obscure information, with the challenge of producing information that is understandable for the average citizen.

CONCLUSION

The organizational transparency construct is still at development. Not only the operationalization but also the consequents and antecedents have to be better understood by governments, organizations and society alike. Notwithstanding, there is a clear demand for transparency for both government and organizations. This is a point of no return. The tendency is for an even greater call for transparency of all kind of data and information produced by the organizations and governments.

In this regard, increasing transparency can strengthen the lines of accountability between government and citizens. That is, when citizens are better informed about the governmental performance, citizens are more capable to pressure public officials to perform their duties in the public interest (Shah and Schacter, 2004). However, legislative or constitutional commitment to transparency does not magically lead to the informed, deliberative, and/or participatory citizens (Fenster, 2006). The correct allocation of public resources and the dissemination of public information is crucial, not only to meet the legislation in force, but also to be accessible to all citizens who have the right to know how public money is being used (Oliveira & Maciel, 2013).

Nevertheless, the search for an equilibrium point of between full disclosure and secrecy, carefully weighting the relative costs and benefits of transparency in each context, is a very important issue. There should be special efforts to define what kinds of governmental decisions, data and political participation are most likely to benefit from transparency, while also considering what costs and dangers government and institutions will face as the result of complying with the transparency requirements. Unfortunately, this does not seem to be the norm nowadays. According to Fenster (2006), this discussion about the need of equilibrium for transparency has not been sufficiently considered in academia or governments.

Agreeing with the various sources consulted, one can conclude that the simple disclosure of information is far from being transparency. Christensen & Cornelissen (2015) indicate that the exact relationship between transparency, openness and information are often unclear. More important is to note the even though organizational openness is a precondition for transparency; it is insufficient for true transparency, since the mere disclosure of information does not consider the capacity of the (multiple) receivers to process the information disclosed.

Thus, the disclosure, the clarity and accuracy of the information are dependent on the receptor or user of the information. Thus, some stakeholders may consider an organization transparent, while the same organization may seem opaque to others. It only will be truly transparent when all conditions for transparency have been met: completeness, understandability and reliability.

KEY TERMS AND DEFINITIONS

Disclosure of Information: The act of making relevant information about the organization readily available to its stakeholders.

Opaque: Quality of an organization or data not being transparent, usually used as the opposite of transparent.

Openness: Quality of being open, transparent and available.

Process Transparency: The existence of a defined organizational policies to disclose information to the stakeholders, subject to criteria of the information being accessible, able to be used, well presented, prone to be understood and auditable.

Target Transparency: Selective disclosure of information by organizations to reduce risk or performance issues.

Transparency: The propriety of disclosing information to the stakeholders that is complete, reliable and understandable.

Transparent Organizations: Organizations that disclose information about its activities, process and all relevant information to its stakeholders.

INTRODUCTION

Web 2.0, which represents a major evolution of the regular Web (*aka* Web 1.0), provides Internet users with a set of technologies (e.g., AJAX and JSON) and applications (e.g., Facebook and Twitter). It aims at increasing communication, collaboration, and knowledge sharing among multiple stakeholders (Yahya, Boukadi, Maamar, & Ben-Abdallah, 2015). To tap into these Web 2.0's opportunities, enterprises are putting a lot of efforts into adopting Web 2.0 in their day-to-day operations. These enterprises are referred to as *Enterprise 2.0* (Mäntymäki & Riemer, 2016).

More specifically, an Enterprise 2.0 is characterized by the use of Web 2.0 technologies and applications to achieve different goals (McAfee, 2006) like improving its visibility on search engines, reducing the cost of some services such as communication, improving the quality of services it provides especially those related to customer satisfaction, etc. It may also use Web 2.0 to enhance transparency by enhancing the availability of information and knowledge across its organizational units (DiStaso & Bortree, 2012).

To reach its goal, an Enterprise 2.0 may need to "re-engineer" its Business Processes (BP) due to the new context imposed by Web 2.0. The resulting business process, called Social Business

Process (SBP) (Yahya et al., 2015), differs from the classical business process in two main aspects: On the one hand, the new interactions over Web 2.0 should be integrated into the SBP model so that "to-be" *versus* "as-is" processes are aligned: on the other hand, the business and social aspects of an SBP should be modelled separately so that the "separation-of-concerns" principle is supported. The business aspect may be represented using any existing notation like UML activity diagram (OMG, 2011b) or Business Process Model and Notation (BPMN) (OMG, 2011a). However, the social aspect is not supported by existing notations and thus should be modelled using a Domain Specific Language (DSL) that extends any existing business process modelling language. To provide for such DSL, we first enrich the BP meta-model proposed in (Curtis et al., 1992) with social aspects. Secondly, based on the obtained meta-model, we develop a BPMN extension, called BPMN4Social, for modeling SBP. BPMN4Social is a simple, yet generic domain-specific language that is based on BPMN, the de facto standard for business process modelling.

The remainder of this chapter is structured as follows. Section 2 discusses works related to SBP. Section 3 introduces our SBP meta-model which we produced by enriching the business process meta-model with social concepts. Section

4 presents BPMN4Social including its meta-model and concrete syntax. Section 5 illustrates the BPMN4Social notation supported by its editor. Finally, Section 6 summarizes the chapter and outlines future works on SBP.

BACKGROUND

The business process meta-model of Curtis et al. (Curtis, Kellner, & Over, 1992) is the most referenced business process meta-model by the ICT community (Figure 1). It encloses the core business process components classified into four perspectives: functional, organizational, behavioral, and informational. The functional perspective focuses on the tasks in a business process where a task is either an atomic or composite unit of work. The organizational perspective describes the units that participate in the business process execution. The behavioral perspective represents the flows and control nodes linking the tasks of the business process. Finally, the informational perspective describes the entities that a business

process produces or manipulates. These entities could be events, information resources, or tangible resources. These four perspectives are commonly modeled using BPMN (OMG, 2011a).

RELATED WORK

In this section, we present the most important works dealing with social business process management systems (BPMS) and those focusing on Social Business Processes.

Web 2.0 and Business Process Management Systems

In the literature, different studies highlight the role of Web 2.0 in improving traditional BPMSs. According to Schmidt et al. (Schmidt & Nurcan, 2009), weak ties, egalitarianism, social production, and service-dominant logic principles of Web 2.0 would address four well-known BPM problems: model-reality divide, lack of information fusion, information pass-on threshold, and lost innovation.

Figure 1. Business process meta-model

For instance, weak ties should help enterprises capture the necessary knowledge for improving their BPs and thus, preventing problems of lack of information fusion and loss of innovation (Schmidt & Nurcan, 2010). Schmidt et al., also, argue that egalitarianism combined with service-dominant logic ensure the involvement of final users in a process's lifecycle (i.e., modeling, implementation, execution, and evaluation) and thus, reduce the risks of model-reality divide where "to-be" *versus* "as-is" processes are not aligned. Furthermore, social production helps generate knowledge by collecting information from different participants in an uncontrolled way so that the problem of information pass-on threshold is addressed.

Erol et al. (Erol et al., 2010) argue that social software (i.e., Web 2.0 applications) allows the integration of all internal and external business actors into the BP lifecycle in order to reach an operational and flexible BP model. In particular, social software offers tools that various internal and external actors can use to collect knowledge, which can be utilized in the continuous improvement of the process. Yet, the authors recognize that social software can raise some security challenges.

Rangiha et al. (Rangiha & Karakostas, 2013) propose a goal-oriented approach to define a Social BPMS (SBPMS) that uses social software to engage final users in the BP lifecycle. This work addresses the lack of an effective method for enhancing BPMS with social software especially during the enactment stage. As a result, they introduce goals starting at the modeling stage to act as controls. Thanks to the goals, users can specify the sequence of tasks to be performed when executing processes.

All of the aforementioned approaches concentrate only on the ability of social software to improve BPMS without considering their ability of improve the business processes themselves. In fact, the improvement of BPMS will result in the improvement of the business processes; however, it does not guarantee the establishment of social business processes (Yahya et al., 2015).

Web 2.0 and Enterprise Business Processes

Brambilla et al. (Brambilla, Fraternali, & Vaca, 2011) propose a social network-based extension of BPMN to model SBP. The proposed notation extends the following BPMN elements:

- The BPMN pool is extended by three types of pool named internal performer, internal observer and external observer;
- The BPMN task is extended by several specific tasks such as commenting, invitation to activity, and voting.
- The BPMN gateway is extended by two specialized decisions, which are choices performed by users or automatically; and
- The BPMN event is extended by several specialized types of events like social relationship link and an invitation's acceptance/rejection.

Being closely related to social networks, this proposed BPMN extension therefore allows to model SBPs that use only a social network as Web 2.0 application. Besides this SBP notation, Brambilla et al. also propose a technical framework that allows the design, implementation, deployment, and monitoring of SBPs. In the implementation phase, the proposed framework allows enterprises to implement SBPs as Web applications connected with any social network.

In 2014, IBM proposed seven repeatable patterns that may be used to add social capabilities to business processes (IBM, 2014). Each social pattern is described in terms of: the concerned business processes, relevant industries, key stockholders, recommended actions, business challenges, potential benefits as well as the IBM experience. The proposed social patterns are applicable by organizations in various industrial sectors. However, the patterns are informally described and do not offer any guidelines for their application.

Cerenkovs et al. (Cerenkovs & Kirikova, 2014) propose an iterative, incremental development

process for incorporating social interaction within business processes. Their development process consists of four phases: inception, elaboration, construction, and transition. The inception phase provides recommendations, which could assist the enterprise assess BP socialization feasibility. The second phase models the SBP using BPMN language. The social aspect of the SBP is represented using Brambilla extension (Brambilla et al., 2011). The third phase implements the SBP. Finally, the fourth phase executes the new SBP. While the proposition of Cerenkovs et al. covers the core phases of the development process, it informally specifies the four phases and it does not provide any information about the used techniques, standards, nor implementation of the process.

SOCIAL BUSINESS PROCESS META-MODEL

To offer an adequate BPMN extension that supports the social dimension of a business process, we define an SBP Meta-Model called SBP2M. We constructed SBP2M by enriching the business process meta-model of Curtis et al. (Curtis et al., 1992) with a social aspect. We have chosen this meta-model because it is widely used in the literature as a reference for modeling different types of processes. For instance, List and Korherr extend it with a fifth aspect, called context aspect, to describe contextual information of a business process like goals, owner, and deliverable (List & Korherr, 2005). Chaâbane et al. also extend it to support business process versioning (Chaâbane, Andonoff, Bouaziz, & Bouzguenda, 2009). Ellouze et al. extend it to support inter-organizational business processes (Ellouze, Chaâbane, Andonoff, & Bouaziz, 2015).

In this chapter, we illustrate how to enrich Curtis et al.'s business process meta-model so that it supports the social dimension of an SBP. Figure 2 shows the proposed meta-model where the new concepts are represented in grey:

1. The functional aspect is enriched by social task that is either atomic or composite. A social task is executed by a Web 2.0 application (e.g., post advertisements on Facebook).
2. The organizational aspect is enriched by social actor, which describes those who will perform social tasks. A social actor may be either human (internal or external to the enterprise) or a Web 2.0 application.
3. The informational aspect is enriched by social concepts like Web 2.0, social event, and social data object. A social task may produce zero or many social events. In addition, a social task manipulates or produces social data object (e.g., advertisement data) that could be made available over Web 2.0.
4. The behavioral aspect is enriched by a social decision that is made over Web 2.0 applications and it is represented inside the SBP model as a control node. The behavioral aspect is also enriched by a social flow to describe the interactions that take place between actors over Web 2.0 applications. For example, a social flow can be used to model the link between posting task and the corresponding commenting and collecting feedbacks tasks.

Thanks to SBP2M, the different business entities that socialization could affect can be explicitly described (e.g., task, event, and information resource). The next section focuses on modeling SBP, which considers the social dimension of a business process.

BPMN EXTENSION FOR SOCIAL BUSINESS PROCESS MODELING

In this chapter, we propose BPMN4Social, which is a specific notation for SBP modeling. BPMN4Social distinguishes social from business elements, and it represents social interactions in the SBP model. Our aim is to provide a simple, yet generic notation that can be used easily by busi-

Figure 2. Social Business Process Meta-Model (SBP2M)

ness analysts and independently from any Web 2.0 application. On the one hand, the simplicity of the notation is ensured by reducing the number of new extensions. On the other hand, technology independence is ensured by not targeting any particular Web 2.0 service (e.g., commenting votes and chatting services) when defining the extension. The meta-model of BPMN4Social is detailed below.

BPMN4Social Meta-Model

Before presenting the BPMN4Social meta-model, let us first introduce the mapping of SBP2M social concepts onto BPMN4Social concepts. In Figure 3, only the relevant classes of the BPMN meta-

model are shown in white while BPMN4Social classes are shown in yellow.

1. SBP2M social actor is mapped onto three different social lanes:
 - a. **Social Internal Lane:** This extension models internal departments of the company that use Web 2.0.
 - b. **Social Customer Lane:** This extension models individual customers of the company, in the case of B2C, who use Web 2.0.
 - c. **Social Community Lane:** This extension models the partners of the company that use Web 2.0. Each new lane is characterized by two supplementary attributes:

- i. **Technology:** It identifies the used Web 2.0 application.
 - ii. **Type:** It distinguishes between authenticated and anonymous users.
2. SBP2M social activity is mapped onto four different social activities:
 - a. **Communication Activity:** It models communication activities such as the exchange of messages between the various internal and external actors.
 - b. **Collaboration Activity:** It models the collaborative activities, such as joint drafting activities, among the various internal and external actors.
 - c. **Collecting Activity:** It models activities that allow the collection of information and knowledge using Web 2.0. Such an activity may be used to collect customers' feedback.
 - d. **Sharing Activity:** It models activities that allow the sharing of information and knowledge using Web 2.0. Such an activity may be used to share knowledge with various actors whether known or unknown in advance. Each new activity is characterized by four additional attributes:
 - i. **Technology:** It identifies the Web 2.0 application used to execute the social activity.
 - ii. **Social Service:** It describes the service provided by the Web 2.0 application (e.g., messaging and commenting) that permits the accomplishment of the social activity.
 - iii. **Input Data:** It describes the data required to accomplish the social activity.
 - iv. **Output Data:** It describes the data produced by the social activity.
3. SBP2M social event is mapped onto two different social events:
 - a. **Send Social Notification:** It models the notification of an actor to participate in a new social activity. The sender of a social notification can invite the receiver to execute some tasks. A social notification is communicated through the used social software.
 - b. **Receive Social Notification:** It waits until a new notification is received from a participant through the used social software. These two new notifications have two additional attributes:
 - i. **Technology:** It identifies the used Web 2.0 application.
 - ii. **Social Service:** It describes the service provided by Web 2.0 that permits the reception or the transmission of the notification.
4. SBP2M social data object is mapped onto BPMN4Social social data object:
 - a. **Social Data Object:** We define a social data object as an extension of the BPMN data object to model the data required or produced by social activities. A social data object has two additional attributes:
 - i. **Type:** It identifies the type of social data object. It may be for example a text, an image, a video, etc.
 - ii. **Criticality:** It allows distinguishing between critical data, which require setting up specific security procedures, from general data.
5. SBP2M social decision is mapped onto BPMN4Social social decision:
 - a. **Social Decision:** The social decision notation allows the modeling of distributed decision made by different actors through Web 2.0. A social decision has three additional attributes:
 - i. **Technology:** It identifies the Web 2.0 application used by the SBP

- ii. **Social Service:** It describes the service provided by the used Web 2.0 application that permits distributed decision-making.
- iii. **Participant:** It describes the different actors that must be involved in the decision making process. An actor may be internal (e.g., company employees) or external (e.g., customer and partner).

as a result, it enforces the separation of concerns principle.

We implemented a graphical editor supporting this syntax as shown in Figure 4. This editor extends the BPMN palette with new components. Each new component is created as a customization of a standard BPMN element. The attributes of each new concept are accessible, like standard attributes, via the property sheet relative to the selected concept.

Graphical Editor

Figure 4. shows the concrete syntax of BPMN-4Social, which defines a visual representation for the proposed BPMN extensions. This syntax has two advantages: it is simple to use thanks to the limited number of new notations that are added to the standard BPMN; and the new concepts of BPMN4Social have a different representation and,

CASE STUDY

To illustrate the use of our graphical editor along with the benefits of the proposed extensions, we consider the maintenance business process of a large commercial company. This business process is triggered when an employee's device breaks down. The employee of the device sends a complaint to the maintenance department. Two

Figure 3. BPMN4Social meta-model

Figure 4. Graphical editor of BPMN4Social

scenarios are possible: success or failure. In the first case, the maintenance department informs the employee that the problem is fixed and then prepare and submit a report to the administration. In the second case, the maintenance department submits a report to the administration that identifies some external support. Once identified, the administration sends the report to external stakeholders. These latter prepare and send a technical report to internal experts. Internal experts examine the technical report and can accept or refuse the preposition. The maintenance BP model is depicted in Figure 5.

The maintenance business process could benefit from Web 2.0 applications. Indeed, these applications could keep users and experts connected and engaged in the progress of this business process. Web 2.0 applications could be also used by the administration to find the most adequate stakeholders. To this end, administration can use

LinkedIn a Web 2.0 application. Last but not least, experts and external stakeholders can use Web 2.0 to examine and solve the problem collaboratively.

If the maintenance business process had to be modelled using a standard modeling language like BPMN, the distinction between *social* and *regular* interactions would not be clearly illustrated. Yet, by using our graphical editor, the model is clear and developers can easily distinguish social interactions and activities thanks to the new notations. Therefore, BPMN4Social models the socialized version of this BP by first, illustrating the communication between users and experts using communication activity. Second, modeling the search for an adequate stakeholder using collecting activities. Finally, introducing the collaboration between, experts and external stakeholders using collaborative and sharing activities. As such, we added social lane within each pool that will contain social activities. The choice of the nature of

Figure 5. Maintenance business process

the social lane is determined by the nature of the original pool. For instance, as users, experts, and administration are internal actors, we added within their pools a social internal pool while we added a social community lane within the stakeholder pool. Figure 6 shows the maintenance business process modelled via the use of BPMN4Social.

FUTURE RESEARCH DIRECTIONS

As a future endeavor, we plan to implement an automatic code generator that generates an executable code from the social business process model. The generator will be built upon model transformations a la Model-Driven Architecture

Figure 6. Maintenance business process modelled with BPMN4Social

(Soley, 2000). In addition, we plan to propose an approach that helps enterprises blend social software with their existing BPs so they can tap into the opportunities of social media. This will help an enterprise identify business processes that could benefit from socialization while meeting the enterprise goals and requirements. It will also transform automatically the identified business processes into social business processes.

CONCLUSION

Web 2.0 enhances business processes with new functionalities that improve the exchange of knowledge and information between various actors (Zhu & Chen, 2012) (Paniagua & Sapena, 2014). Thanks to Web 2.0 applications, new communication forms between enterprises and stakeholders are created (Fortino & Nayak, 2010). In fact, several studies have shown the added value of Web 2.0's practices inside the enterprise like improvement of enterprise productivity thanks to collaboration between actors (Bennett, 2012) (Zhu & Chen, 2012) (Jussila, Kärkkäinen, & Aramo-Immonen, 2014). The combination of business and Web 2.0 incurs to several changes in business processes and thus social business processes are rolled out. Social business processes are different calling for new ways of modeling, designing, and executing them. These new social elements must be represented explicitly through a specific notation during the modeling stage.

In this chapter, we proposed SBP2M, a meta-model for social business processes. SBP2M is the result of enriching the business process meta-model of (Curtis et al., 1992) with the social aspect. Based on SBP2M, we developed a BPMN extension for modeling social business processes. The proposed DSL extends BPMN visual language with new notations like collaboration and sharing activities, which express social interactions between actors. These new notations are defined as a customization of the standard BPMN notation.

This extension is characterized by its simplicity and independence from Web 2.0 technology. Our graphical editor is implemented as an extension of BPMN2 modeler.

KEY TERMS AND DEFINITIONS

Social Business Process: It is “a BP that uses any Web 2.0 technology or application to achieve the enterprise business goals and to foster

communication, collaboration, and exchange of knowledge either among internal or with external actors in everyday work” (Yahya et al., 2015).

Social Media: Kaplan and Haenlein define social media as “a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user generated content.” (Kaplan & Haenlein, 2010).

Web 2.0: Constantinides and Fountain define Web 2.0 as “a collection of open-source, interactive, and user-controlled online applications expanding the experiences, knowledge, and market power of the users as participants in business and social processes. Web 2.0 applications support the creation of informal users’ networks facilitating the flow of ideas and knowledge by allowing the efficient generation, dissemination, sharing and editing/refining of informational content” (Constantinides & Fountain, 2008).

Social Issues in IT Project Teams

B**Awie C. Leonard***University of Pretoria, South Africa***D. H. Van Zyl***University of Pretoria, South Africa*

INTRODUCTION

The role and impact of social issues in IT project teams should not be underestimated. With the involvement of virtual project teams, this is even more relevant. One such social issue is the establishment of relationships between members of teams. The establishment and maintenance of social relationships and networks in the IT project environment is a phenomenon all IT professionals are exposed to and in many cases involved in. Furthermore, these relationships are used by IT project team members for personal as well as professional purposes. The question is what (negative or positive) impact such social relationships and networks might have on the success or failure of any given IT project?

The objective of this chapter is therefore to emphasize the important role social relationships and networks play in the IT project team environment. Furthermore, to illustrate to the management (project managers and project leaders) of software project teams how such relationships can have a positive or negative impact on team members. In this regard a climate or culture should be allowed for these relationships to flourish to the benefit of the IT department.

BACKGROUND

The IT project management literature is extensive with regard to success factors as well as the

causes of failure; however, little focus is placed on the role or importance of social relationships and networks within IT projects.

Liebowitz (1999) feels that the greatest threat to the success of any IT project is the failure to communicate. This statement in particular draws the attention to the problem area of the research. Although one wants to see a project environment where a culture of sound communications is promoted, it is difficult for any project manager to “control” any influence this might have on team members and as such on the progress of a given project. Sauer (1993) believes that a major part of the problem of IT project failure is the lack of recognition that information systems development is largely a social and political process. This view is also shared by Standing (1998). Considerable effort has already been spent on the process of managing IT projects and has produced multiple methodologies and methods for project management and the IT software development life cycle (Standing & Bavington, 1996). This is further complicated by the fact that virtual teams are in particular an area of great risk as pointed out by Reed & Knight (2010). According to them, the lack of project team cohesion can impact seriously on team performance. Problems with team cohesion can occur when there is conflict between team members or when the relationships necessary for the team to function do not develop.

Ashworth and Carley (2006) state for example that “Social network theories suggest that the types and degrees of an individual’s relationships

in social and communication networks are key impactors of group performance, while resource dependency theory suggests that non-social factors, such as knowledge and skills, figure at least as prominently as social dimensions in determining such performance.”

In organisational theory, managers are viewed as contributing over and above the skills they have acquired through experience and education, the value of their social networks. These values or assets refer to the social capital of the manager. Scholars have highlighted the ability of these social networks that can be used to the individual’s or organisation’s advantage (Gargiulo & Benassi, 2000; Ashworth & Carley, 2006). With this in mind, the question is how social relationships and networks within IT project teams are viewed, instead of focusing only on that of the project managers. The social capital of the individuals participating in the IT project teams is an influencing factor on the social networks that are active within the project teams.

The first consideration is that of determining the strength of these social networks. Network strength can be defined as the frequency of communication, while the degree of the network is defined as the number of direct links with other network members (Monge & Contractor, 2003, cited in Hovorka & Larsen, 2006).

Social networks have a key function in the social information processing within an organisation,

especially relating to connecting social influence, knowledge and the organisational culture to the actual projects at hand. This influence is depicted in Figure 1.

In the rest of the chapter a brief theoretical analysis of the field is described as well as a brief description of the empirical research.

A THEORETICAL BACKGROUND ON SOCIAL RELATIONSHIPS AND NETWORKS

Relationships between end users and team members of information technology (IT) projects are described by Leonard (2002) as intriguing and complex. According to Leonard a large number of elements (amongst others support; cooperation; knowledge and commitment) are involved during the establishment and maintenance of sound relationships. Furthermore, he argues that if any of these elements are disturbed, the whole relationship is disturbed. In other words, these elements form an holistic “unit.” Each of these elements therefore plays a specific social role in a relationship, which impacts on the soundness of a relationship and as such on the cooperation between team members.

In order to overcome the problem of poor relationships between IT professionals and end users, for example, it is argued that a “human-behaviour” strategy of some kind should be followed. This strategy should involve amongst other things focusing on those social issues that will enhance trust, commitment, co-operation etc. Reich & Benbasit (1999, referred to by Leonard (2002)) point out that there are two dimensions to strategy creation: the intellectual dimension and the social dimension. With regard to this research, the social dimension was the focus.

Sound social relationships could be regarded as an important ingredient for any working environment. Not only between employees in general, but also for the purpose of organisational learning and support.

Figure 1. Interaction of network strength and social information processing
Source: Hovorka & Larsen, 2006

Trust

Although all the elements mentioned by Leonard (2002) are important for the establishment and maintenance of sound relationships, it is noteworthy that the element of trust could be regarded in most cases as the basic ingredient for sound relationships, and therefore more theory is given in this regard.

Trust is an important component in social relationship building, but it remains a complex and ambiguous phenomenon (Kadefors, 2004). Kadefors defines trust as: “Trust is a psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behaviour of another.” This definition implies that trust is not a behaviour, but rather a psychological state. Furthermore, Kadefors explains that trust is not a prerequisite for cooperation, but the presence of trust improves and extends the level of cooperation.

Trust becomes important in IT projects due to the high level of cross-functional members that participate in IT projects and the associated fundamental need for cooperation. Required trust levels are directly affected by the situational circumstances and the team dynamics within IT projects. Finding the right balance of trust is important, as there are costs associated with trust (Kadefors, 2004):

- Direct costs are associated with the building of trust.
- Potential costs of breaching trust.
- Costs resulting from inefficiencies due to excessive levels of trust.
- Trust can be created by the following methods:
 - **Relational Trust:** Relational trust is created through repeated interaction between individuals. Trust is based on the personal experiences of individuals and their interpretation of events.

- **Calculus-Based Trust:** Calculus-based trust results when the trusting party believes that the trusted party will deliver on the promised actions, as this delivery is in the financial interests of the trusted party.
- **Institution-Based Trust:** Trust is created through institutions, such as legal systems, regulatory systems and societal systems. These systems are very much context-related and the levels of trust can thus differ, based on their context.

Trust is thus a context-based psychological state that is affected by the participating individuals, as well as the associated circumstances. Kadefors (2004) explains it in the following way: “We trust a colleague or exchange partner in some situations but not in others, and decisions on whether or not to trust are continuously revised in the light of new information.”

In the next part of the chapter the empirical research is presented (based on project charter and project closure documentation) to illustrate what social activities take place in a typical IT project environment.

EMPIRICAL RESEARCH

A large South African financial bank was chosen for the investigation. The motivation for using this bank was because of the large number of on-going projects that exist at any given point in time. This bank also undertakes a considerable number of IT projects on an annual basis.

Information was primarily obtained from project documentation of completed or abandoned projects within the IT departments of the corporate bank. A survey was created, based on the initial findings of the grounded theory research, and these findings were then sorted into categories.

Based on the information analysed during the initial literature review and personal experience, the following question was formulated: Do the social relationships and networks within project teams and external to these teams influence the outcome of such projects? During the grounded theory process the following secondary questions were identified and addressed:

- How are social networks used?
- Do separate and distinct social networks develop within project teams?
- Do pre-existing social relationships and networks between potential team members influence the dynamics of a new project team?
- What factors outside the project team have an influence on the social relationships and networks?

To answer the above mentioned questions, the empirical research process took the form of reading through a large number of relevant project documentation. At the same time data was arranged, categorised and analysed. Answers to certain research questions emerged and a comparison with existing literature was done. In the following section a theoretical background is given, as well as how the empirical research process took place.

The survey utilised in the research is classified as a cross-sectional survey, as it involves approaching a sample of respondents only once. The sample is regarded as a cross-section of the population under study. The survey results were used to compare subgroups (such as project managers and developers) and evaluate relationships between variables.

The target population for the survey was limited to members (project managers, developers and other participants in IT projects) of two case studies. The survey was distributed to 100 possible candidates in the form of a self-administered Internet questionnaire.

The Likert Scale was used to measure the participants' views on the categories identified during

the initial data collection phase. The Likert Scale allows for interval scales and a full spectrum of statistical analysis. A deductive interpretavistic approach was applied to analyse the results of the survey.

The data used for the initial Grounded Theory (GT) process was obtained from project documentation. These documents consisted primarily of project charter and closure documentation. The data was used to identify the concepts and categories during the data collection phase of GT. Further information relating to the concepts and categories were obtained using a survey distributed to participants from the two selected case studies which is briefly described in the next section.

Case Studies

The two case studies used for the GT process are based on two different IT environments. The first case study refers to the primary centralised approach and the second case study relates to a decentralised approach. The two environments where the case studies took place, are just briefly discussed because of space limitations.

IT Environment 1 (Case Study 1)

In the first case a Technology Program Office was created by the bank to provide integrated end-to-end management services for the strategic project portfolio. The bank makes use of program management to control the myriad of projects executed concurrently within its environment. The project management methodology was based on the PMI PMBOK. All nine knowledge areas are implemented, but tailored to the bank's environment.

IT Environment 2 (Case Study 2)

The second case focuses on the bank's Personal Loans Information Technology division, which is a full-fledged IT department that services the needs of the Personal Loans business division

within the bank. The primary focus of the team is to provide and maintain information systems that cater for the specific needs of the Personal Loans mono-line. Their approach to project management was similar to that of case study 1.

Analysis of Data

The ATLAS.ti software was used to perform the GT data ordering, data analysis and theory development phases. Furthermore, the process was used to identify the impact areas as well as the impact types of social relationships and networks.

Impact Areas

The impact areas (with their related issues) of social nature are as follows:

- The role of leadership within the project. The following issues are related to this impact area:
 - The presence of a strong leadership component within the project.
 - Importance of leadership versus procedures.
 - The level of leadership and the project outcome.
 - The level of support for leadership within the project team.
- The project culture. The following issues are related to this impact area:
 - The presence of a recognisable culture within the project.
 - The effect of the project culture on the project team.
 - The role of the project manager in determining the project culture.
 - The project culture versus the organisational culture.
 - The influence of the project culture on the project outcome.
- The social relationships between team members. The following issues are related to this impact area:

- The level of social relationships that develop between team members.
- How the social relationships are used within the project.
- The effect of social relationships on how team members view others.
- The individual's external social networks. The following issues are related to this impact area:
 - Which type of external social networks are utilised?
 - What are the external social networks utilised for?
- External influencing factors on the project. The following issues are related to this impact area:
 - The effect of external factors on the project outcome
 - The types of external factors influencing projects.

These impact areas were used as basis for gathering more data by means of a survey. The survey and key findings are discussed in the next section.

Impact Types

Social relationships and networks are active in IT projects in three primary formats which are called impact types. They are as follows: influence, friendship, and advice:

Influence

Project team members establish social relationships within project team structures over time through their personal interactions. Stronger social relationships can be developed with some team members compared to others which can create areas of leverage for the individuals. These social relationships provide a platform for individuals to influence the project direction or decisions through:

- Influencing the project leadership.

- Influencing other team members to gain support for their own ideas and agendas.
- Using their social relationships to solve problems when project structures and procedure present a stumbling block.
- Influencing the project culture.

Harnessing this influence to the advantage of the project will increase the contribution of the specific individual to be greater than just their knowledge and skills.

Friendships

Some individuals develop social relationships with other project team members to such a level that it evolves into friendships that extend beyond the project structures. These friendships can result in the creation of certain social groupings within the project team that result in the alienation of other project team members, to the disadvantage of the project. Harnessing these friendships in the composition of new project teams can result in the creation of highly effective project teams that deliver beyond the sum of the capabilities of the individuals.

Furthermore, Leonard (2002) states that these relationships has a very intrigue nature. According to him they consist of two dimensions, namely a physical and abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between team members, whereas the abstract dimension describes the soft issues of a relationship. These two dimensions enable one to describe the holistic nature of such a relationship fully and to encapsulate the important elements of a support-oriented organization, namely mutuality, belonging, and connection. Because of the holistic nature of the different elements, Leonard (2002) argues that any kind of change having an effect on any of the elements of either the physical or abstract dimensions of a relationship will in fact disturb the relationship. Based on this, one can

argue that social relationships and networks that are disturbed needs to be managed in such a way that all role players stay focused and committed.

Advice

Individuals make use of their social networks outside of the project structures to gain advice to assist them in performing their tasks and to influence the project. Individuals with strong and influential social networks can be advantageous to project teams as these networks can be used by other team members and to provide validity to the project. These networks can assist greatly to identify possible external factors that could influence the project and develop associated actions to minimize potential negative impacts.

Survey Design and Results

The survey was distributed to 100 participants across the two cases with 58 valid responses received. As stated previously, the Likert Scale was used to measure the participants' views on the categories identified during the GT initial data collection phase.

The purpose of the survey was to:

- Gathering further information to saturate the categories identified during GT.
- Gathering personal views of participants in IT projects.

The survey illustrates clearly the huge role played by the establishment and use of social relationship and networks in a given IT project environment. In summary, the survey indicates the following phenomena:

- In total 87% of the respondents indicated that social relationships between team members developed within the project teams as well as between members of other teams. Almost two thirds indicated that

they developed stronger social relationships with some project team members than with other.

- Social relationships are used by team members within and around the structures created in the project environment.
- Project team members used their social relationships to solve problems whilst following project procedures as well as when the procedures proved to be a stumbling block in resolving the particular problem.
- A significant finding is that one in two respondents indicated that they made use of their social networks outside the organisation to gain knowledge so that they could influence the project.
- A large number of participants indicated that the team members make use of their social relationships to the benefit of the project, but to their individual benefit as well.

SUMMARY OF RESEARCH FINDINGS

Here follows a summary of the major findings.

The nature of IT projects normally requires high levels of team member interaction throughout the project life cycle and thus social relationships will develop between project team members. Two thirds of respondents indicated that they developed stronger social relationships with some team members than with others. This implies that social alignments or clicks can develop within project teams that must be monitored to prevent possible alienation of team members. Harnessing these groupings to the advantage of the project can provide momentum and energy toward successful project delivery. Some social relationships developed between project team members to such an extent that team members developed friendships that extended beyond the project environment. Although this phenomenon is on a personal level, this could also enhance or hamper performance which needs to be monitored.

Project team members use their social relationships primarily to solve problems and to gain some level of advantage. This could be regarded as a positive development in the sense that team members will, because of certain relationship, deal with their problems as quickly as possible and enhance the team performance as a whole.

External relationships and networks also play an important role. These social networks can be of a formal or informal nature. Formal networks include for example industry portals, special interest groups, past colleagues and information feeds, whilst informal networks include blogs, search engines and social networking tools. Individuals can also be used by other members in their social networks to influence the IT project. Influential business people can influence projects by accessing project team members directly and thus bypassing project structures. Such interventions must be monitored as it could negatively impact on the project direction or results.

In terms of the strong phenomena of the use of virtual teams all over the globe, management must do some risk management. They must identify those issues that are particularly possible to impact negatively on relationship development. While collaboration technologies have the capability of creating a communication environment for virtual partners who are separated by time and/or space, they may hinder the development of a strong sense of cohesion and satisfaction with the group's interaction process. Second, the strength of relational links is positively associated with the effectiveness of information exchange. Therefore, the loss of relationship building in virtual teams implies that the use of traditional meetings as a supplement to the use of electronic means might be useful (Warkentin *et al* (1997)).

SOLUTIONS AND RECOMMENDATIONS

This research identified impact areas as well as impact types of social relationships and net-

works on IT projects. These impact areas and types need to be considered when project teams are established as well as monitored throughout the project life cycle. Taking cognisance of the importance of social relationships and networks within IT projects can improve the management of technology and ultimately contribute to a greater success rate of IT projects.

The results of this research put a very important obligation on project managers' shoulders to take responsibility for these relationships and to "allow" them for the benefit of each project and as such for the organization. One can argue that such relationships enhance easier communication regarding issues that are normally not discussed in a more formal project environment. Here one can for example think of issues that need "whistle blowing." This brings us back to the importance of creating a project culture that should portray the following: "Instead of shooting the messenger, managers would do well to establish ...climate that encourages individuals to come forward with accurate project status information, regardless of whether the news is good or bad" (Smith & Keil, 2003). Therefore, social relationships between IT professionals of different teams as well as with other employees in the organisation are important to investigate on a deeper level. Furthermore, discussions between practitioners and academics should be encouraged to explore their impact on the normal operations of an IT department and ways to manage it in a professional way.

FUTURE RESEARCH DIRECTIONS

The impact of social relationships on project failure or success, is a very complex issue. This research has illustrated that these relationships are very important to team members and that they use it for different reasons of which the most important is to support them in solving problems. What is needed and unclear about these relationships is their impact and role with regard to project success or failure. One can for example argue that

such relationships enhance easier communication regarding issues that are normally not discussed in a more formal project environment. Here one can for example think of issues that needs "whistle blowing." This brings us back to the important issue of a project culture that should portray the following: "Instead of shooting the messenger, managers would do well to establish an organizational climate that encourages individuals to come forward with accurate project status information, regardless of whether the news is good or bad" (Smith & Keil, 2003). Therefore, social relationships between IT professionals of different teams as well as with other employees in the organisation are important to investigate on a deeper level.

CONCLUSION

The results of the research illustrate that project management philosophies and methodologies alone are not enough to achieve project success and that the social relationships and networks of project team members cannot be ignored. Each project team member contributes more than just their knowledge and skills to the project. Social relationships and networks will develop and evolve within IT project teams and need to be harnessed to the advantage of the project to improve the likelihood of a successful outcome.

The chapter emphasizes the important role of social relationships in the IT project environment. The results put a very important obligation on project managers' shoulder to take responsibility for these relationships and to allow it for the benefit of each project and as such for the organization.

KEY TERMS AND DEFINITIONS

Grounded Theory: Although this kind of research approach is complex; one can briefly say that it means to develop your theory based on what you find in the existing data. The theory is therefore “grounded” in the data and this is called an inductive process.

Information Systems: Systems that are used by organisations to support them in decision making. These systems provide information to all levels of management in an organisation. These systems are normally the end result of an IT project.

Information Technology (IT) Projects: Projects that are launched to develop an information and communication technology system or to provide any kind of ICT service to an organisation based on a specific need.

Project Culture: The way people in a specific project think and apply their values. It impacts

on their behaviour and how they perform their responsibilities during the project life cycle. A project culture is normally based on the belief (value) system of a group of people or that of the organisation.

Project Team: A team of people that are responsible to do all the work that is necessary to take a project from its initiation until it is completed.

Social Networks: The group of people or staff that are involved in a relationship for a specific reason. For example, a social network of people having a discussion each week to discuss technical issues regarding a specific project.

Social Relationships: The relationships (professional or personal) that are established during the project life cycle between employees of different teams or the same team or other parts of the organisation.

Virtual Teams: Virtual project teams, by definition, are groups of people working together toward a common goal. Whether, they are called virtual or distributed, the team members are not co-located; they can reside in different cities, states or countries.

Viewpoints on Business Process Models

Giorgio Bruno

Politecnico di Torino, Italy

INTRODUCTION

A business process is a standard way of organizing work in a business context (Rummler & Brache, 1995). Business processes cross functional boundaries in that they involve members of different departments; common examples are developing a new product, ordering goods from a supplier, and processing and paying an insurance claim (Davenport & Short, 1990).

Over the past few years a number of viewpoints have influenced the design of notations for business processes (Bruno, 2011). They emphasize the different elements (tasks, business entities and roles) that compose business process models; for this reason, they are referred to as activity-centric, data-centric, and role-centric viewpoints.

Probably, the most popular viewpoint is the activity-centric one, whose standard representative is BPMN (Business Process Model and Notation) (OMG-BPMN, 2011). It considers business processes essentially as orchestrators of operational activities, which encompass human tasks and automatic ones. Human tasks are carried out by participants by means of graphical interfaces, while automatic tasks are implemented with services. Orchestration is achieved through control flow elements, which enforce rigid precedence relationships: in this context, a business process is like a master distributing the work among the participants in the process.

When processes are meant to operate on the entities which form an information system, whose purpose is to enable human participants and/or machines to perform work using information (Alter 2008), focusing on the identification and the ordering of the activities may not be the right way to start with an investigation of the intended business.

The alternative solution proposed by data-centric approaches is to begin with the identification of the key business entities and their life cycles consisting of states and transitions (Hull, 2008). The term artifact has been introduced to designate a concrete and self-describing chunk of information used to run a business (Nigam & Caswell, 2003). The artifact types come from experience and are associated with business goals; the analysis of how to progress towards the goals determines the definition of their life cycles (Battacharya et al., 2005). The major benefit is the right level of granularity, which facilitates communication among the stakeholders and helps them focus on the primary purposes of the business (Chao et al., 2009).

An extension to data-centric approaches is the case-centric viewpoint, whose major purpose is to support knowledge workers in applications requiring the flexibility that cannot be provided by the approaches based on a rigid control flow (Marin, Hull and Vaculín, 2013). Flexibility implies that the participants in the process are no longer considered as mere resources needed to carry out tasks that are not automatable, but they can be involved in a number of choices, such as the selection of the input entities when a task needs more than one and the selection of the task with which to handle the input entities when two or more tasks are admissible (Bruno, 2014).

Human tasks are associated with roles, which represent the participants involved in the processes. However, if the process model shows the activity flows of the roles in a single view, it may be difficult for a participant to understand what their actual involvement is. The participation of users in processes is made more evident if the process is decomposed into several “role” components:

DOI: 10.4018/978-1-5225-2255-3.ch068

this is the essence of the role-centric viewpoint (Ould, 2005).

This article illustrates how the above-mentioned viewpoints can be extracted from a global model, which is based on a notation named iBPN (integrated Business Process Notation). This notation is inspired by high-level Petri nets so as to take advantage of their ability of being state and action oriented at the same time (Jensen, 1997). An example concerning the submission of papers to conferences will be used to illustrate the construction of the global process model and then the extraction of the data-centric viewpoint and the role-centric one.

This article is organized as follows. First it presents background information and the informal requirements of the example to be worked out. Then it illustrates the key modeling issues, the process model related to the example, and the automatic extraction of the above mentioned viewpoints; finally it makes some considerations on future research directions and provides the conclusion.

BACKGROUND

The data-centric orientation is put into practice in two major ways depending on whether the life cycles are defined separately or are combined in a single model. In the first case, various techniques have been proposed to handle the interactions between the life cycles: events and rules in the Guard-Stage-Milestone approach (Hull et al., 2001), macro processes in PHILharmonicFlows (Künzle & Reichert, 2011), hierarchical relationships in COREPRO (Müller, Reichert & Herbst, 2007), and messages in Proclets (van der Aalst, Barthelmess, Ellis & Wainer, 2000). In the second case, the combination of the life cycles gives rise to a data flow which may play a part on the activation of the tasks. The data flow may be the only responsible for the activation of the tasks, as it happens with the iBPN notation presented in this article, or it may act as a complementary

cause with respect to the control flow. The two approaches are referred to as dataflow-centric and extended activity-centric, respectively.

BPMN has been extended with dataflow-oriented features, such as data objects; however, the coexistence of the control flow and the data flow makes it difficult to handle the situations where a many-to-many mapping between entities of different types is needed. An example related to requisition orders and procurement orders is discussed by Meyer, Pufahl, Fahland & Weske (2013).

Extended activity-centric models include all the states of the artifacts involved; for this reason, the life cycles (made up of states and state transitions) can be extracted automatically. The main purpose is to verify the compliance with reference life cycles. Eshuis and Van Gorp (2014) present the extraction of life cycles from UML activity diagrams (OMG-UML, 2015), while the extraction from BPMN models is addressed by Cabanillas, Resinas, Ruiz-Cortés and Awad (2011). The opposite direction, i.e., the generation of process models from life cycles, has also been investigated (Küster, Ryndina & Gall, 2007). Roundtrip transformations between data-centric models and extended activity-centric ones are described by Meyer and Weske (2014).

The Guard-Stage-Milestone approach provided a good foundation for the recent standard CMMN (Case Management Model and Notation) (OMG-CMMN, 2014). Case management involves taking actions regarding a subject in order to achieve a desired outcome. The important issue is that the actions cannot be anticipated in a predefined sequence of tasks. In fact, the case workers may perform the run-time planning of the tasks to be carried out. A short history of the key concepts of CMMN is provided by Marin, Hull and Vaculín (2013). Various flavors of case management are illustrated by Marin, Hauder and Matthes (2015).

Human choices have been addressed by research on flexible processes based on declarative approaches. For example, in Declare any task of an ad-hoc process may be performed as long as

the mandatory constraints are not violated (van der Aalst, Pesic & Schonenberg, 2009).

With the role-centric viewpoint, business processes result from the composition of a number of role components, which are structured as processes: in addition to the tasks pertaining to the corresponding role, they include control flow elements and send/receive operations. The latter are needed to coordinate the various role components involved in the process. Examples of role-centric notations are Role Activity Diagrams (RADs) (Ould, 2005) and Subject-oriented Business Process Management (S-BPM) (Fleischmann and Stay, 2012).

INFORMAL REQUIREMENTS OF THE EXAMPLE

The process under consideration is called Handle-Submissions and is meant to handle the submission of papers to a conference. An informal definition of its requirements is as follows:

1. When the process is started, the chairman has already been appointed and the reviewers have already been identified. In addition, four deadlines, d1, d2, d3 and d4, have already been established; d1 is the end of the submission period, d2 is the end of the reviewing period, d3 is the term for notifying the acceptance or rejection of the papers, d4 is the term for submitting the final versions of the accepted papers.
2. After the start of the process, authors may submit papers before deadline d1; in the same period, they may also update their papers or remove them.
3. At the end of the submission phase, the chairman is enabled to assign the papers to the reviewers; the purpose is to get three reviews for each paper. The chairman produces three assignments for each paper: an assignment is related to one paper and one reviewer and

includes the deadline for completing the review.

4. In case an assignment has not been fulfilled in due time, the chairman produces an additional assignment, which is related to the same paper and directed to a different reviewer.
5. The papers become ready for evaluation when the related assignments have been fulfilled. The chairman decides the acceptance or rejection of the papers before deadline d3.
6. The authors of the accepted papers should provide the final versions before deadline d4; if they do not, the papers are considered withdrawn.

KEY MODELING ISSUES

With the iBPN notation, a business process model is made up of two interrelated models: the dataflow model and the information one. The information model is a UML class diagram (OMG-UML, 2015), which defines the structure (types, attributes and relationships) of the business entities of the domain. The dataflow model consists of tasks which operate on business entities whose types have been defined in the information model. The tight integration between the tasks and the business entities, which is the major purpose of iBPN, is obtained because the behavior of the tasks is specified in terms of constraints and intended effects, which are expressed in a declarative manner with rules and conditions leveraging the elements of the information model. The language used is a simplified version of the Object Constraint Language (OCL) (OMG-OCL, 2014).

Entity Life Cycles

Each entity follows a path (called life cycle) made up of states, from the initial state to a final one. States denote stages of progress through the process and the transitions between states are carried

out by the tasks. In the dataflow model, states are represented by circles called places. Places have two labels: the type name and the state name, e.g., “Paper, submitted”. If the state label is missing, the state is the initial one; final states are denoted by places having no output transitions.

Process Instances and Contextual Entities

When a process is instantiated, the new instance receives a business entity called contextual entity, which provides background information in terms of attributes and associations with other entities. Moreover, all the entities generated during the execution of the instance will be related to the contextual entity, either directly or indirectly. The type of the contextual entity is written between parentheses after the process name, e.g., “process HandleSubmissions (Conference)”.

Mandatory Attributes and Relationships

When a new entity is generated, a number of mandatory attributes and associations with other entities have to be set; they are specified in the information model as follows. Mandatory attributes are qualified by an exclamation mark while mandatory associations correspond to oriented relationships (the source entity type denotes the entities for which the associations are mandatory).

Tasks

A task may be a human one or an automatic one; in the first case, it is depicted as a rectangle with rounded corners, in the second case as an ordinary rectangle. Tasks take the input entities from the input places and deliver the output entities to the output places. If a task generates an output entity, the output link is decorated with the label “new” and the output place corresponds to the initial state

of the entity. Such a task is called generative task for that entity type. The intended effects of tasks are expressed in a declarative manner by means of post-conditions, which are based on the elements (attributes and relationships) of the information model. Restrictions to the execution of tasks are expressed with pre-conditions.

Weights of the Arcs

The weights of the arcs indicate how many input entities are taken from the input places and how many output entities are added to the output places. The weights are integer numbers shown close to the attachments of the arcs to the tasks. If the weight is 1, it is omitted.

Timing Constraints

Tasks may be annotated with timing constraints, such as the “before” clause for human tasks and the “at” clause for automatic tasks. The “before” clause specifies the deadline of the task and the “at” clause the starting time. The actual value is usually obtained from the attributes of the entities visible to the task. The process may be notified when a task is not performed in due time so as to take corrective actions; this feature will be illustrated in the next section.

Performers of the Tasks

Tasks are placed in swim lanes, which are associated with roles: a human task will be assigned to a performer playing the role specified by the swim lane it belongs to. The actual performers may be generic actors or specific ones. A generic actor denotes any actor entitled to play the role needed for the task; on the contrary, a specific actor is an actor who bears a connection to the input entities of the task. For example, any author may enter a paper, but updating a paper is permitted only to the author.

THE PROCESS MODEL AND ITS INTERPRETATION

This section illustrates the model of process *HandleSubmissions*, which results from the above mentioned requirements; it is shown in Figure 1.

Requirement 1 introduces the mandatory properties – the four deadlines and the relationships *Conference-Chairman* and *Conference-Reviewer* – of the contextual entity of the process. Tasks *enterPaper*, *updatePaper* and *removePaper* fulfill requirement 2, and they are all optional.

Requirement 3 is dealt with by tasks *submitPaper* and *assignPaper*. Task *submitPaper* is an automatic one: it is performed at the end of the submission phase and makes all the papers in the initial state leave this state and enter the “submitted” state.

Task *assignPaper* enables the chairman to assign papers to reviewers. The effect of the task is to generate three assignment entities for each paper entity taken from the input place. An assignment entity has to be related with one paper entity and one reviewer entity. For this reason, the mandatory relationships *Assignment-Paper* and *Assignment-Reviewer* are included in the information model. The actual paper entity is the input entity, while the reviewer entity will be decided during the execution of the task. However, the invariants “*paper.assignmentsreviewer in paper.conference.reviewers*” and “*paper.assignmentsreviewer distinct*” guarantee that the reviewers will be selected from among those associated with the conference and that no reviewer will receive the same paper more than once. Task *assignPaper* also sets the mandatory deadlines (attribute *d*) of the newly generated assignments and changes the state of the input papers from “submitted” to “assigned”. The deadline of the assignments is decided by the chairman but the local invariant “*before paper.conference.d2*”, which is written between parentheses after the attribute name in the information model, establishes the upper

limit of the actual deadline. The term “paper” in the invariant denotes the paper the assignment is related to.

Requirement 4 brings about a task (“*makeReview*”) for the reviewer role. For the sake of simplicity, the review provided by the reviewer is not represented explicitly. In case the reviewer does not provide the expected review, the process needs to be notified so as to enable the chairman to make an additional assignment to a different reviewer. Such notifications, called failure notifications, are carried out by means of failure links (shown dashed). If task *makeReview* fails, the input assignment is moved into place (*Assignment, failed*), which is an input place of task *reassignPaper*.

Requirement 5 leads to tasks *admitPaper*, *acceptPaper* and *rejectPaper*. Automatic task *admitPaper* moves an assigned paper to the ready state when there are three fulfilled assignments available for it. The other two tasks change the state of a ready paper into “accepted” or “rejected”, respectively.

Task *finalizePaper* is an optional task enabling the authors of the accepted papers to submit the final versions, according to requirement 6. If an accepted paper is not finalized in due time, the paper is moved to the “withdrawn” state through the default link (shown dashed). A default link is used to inform the process that an optional task has not been performed; default links and failure ones have similar purposes.

In process *HandleSubmissions* there are two cases of human task selection: this kind of selection takes place when two or more human tasks have some or all of the input entities in common. The first choice is between task *updatePaper* and task *removePaper*: this is an optional choice in that the tasks are optional ones. On the contrary, the choice between task *acceptPaper* and task *rejectPaper* is a mandatory one: for each paper the chairman has to decide whether to accept or reject it.

Figure 1. The model of process HandleSubmissions (Conference)

EXTRACTING DATA-CENTRIC AND ROLE-CENTRIC VIEWPOINTS FROM IBPN MODELS

This section shows how the data-centric viewpoint and the role-centric one can automatically be extracted from a dataflow model and presents the results obtained from process HandleSubmissions.

Data-Centric Models

The data-centric viewpoint shows the life cycles of the entity types involved in the process: it may

help analysts check whether the resulting life cycles match those coming from experience or comply with those expected by the organization in charge of running the process.

The dataflow model of process HandleSubmissions deals with two entity types, i.e., Paper and Assignment. Their life cycles are shown in Figure 2. The entity life cycles can be extracted on the basis of a simple rule: for each entity type, say, T, a life cycle model is obtained by first introducing a state for each place of type T and then connecting the states with arcs corresponding to the tasks in the dataflow model. For example, if task

t connects place (T, s1) to place (T, s2), then an arc labeled with t is added from state s1 to state s2. If there is no output place of the same type, as it happens with task RemovePaper, the input state is connected to an implicit final state named “final”. An arc is dashed if the corresponding task is optional.

Generative tasks appear on initial arcs, an initial arc being an arc that has no source state and ends in the initial state. Dashed arcs without task labels, such as initial-failed in the Assignment life cycle and accepted-withdrawn in the Paper life cycle, correspond to failure or default links in the dataflow model. Tasks are prefixed by the initials of the corresponding roles, i.e., A for Author, C for Chairman and R for Reviewer. For the sake of simplicity timing constraints have been omitted.

Role-Centric Models

In the role-centric viewpoint, each role model provides a restricted view of the process limited to the behavior of the role under consideration. This is particularly important when actors external to the organization running the process are involved.

The role-centric models for process HandleSubmissions are shown in Figure 3(a).

Role models derive from swim lanes and have places in common: such places (e.g., “Paper, submitted”) are called inter-role places. A context model, such as the one shown in Figure 3(b), is then provided so as to underline the connections between role models in terms of inter-role places.

FUTURE RESEARCH DIRECTIONS

Given that activity-centric notations such as BPMN provide a mature solution to highly repetitive processes (routines), the focus of current research has shifted to flexible processes in which human choices play a fundamental role.

The new case-centric standard CMMN allows tasks to be selected on the basis of the state of the case being considered; in addition, decisions may be triggered by events such as the availability of a new document, the completion of a task, and the achievement of a milestone. A CMMN model is not a full-fledged data-centric model in that it does not show the entity types involved: this is a

Figure 2. The entity life cycles extracted from the dataflow model

Figure 3. The role-centric models extracted from the dataflow model (a) and the context model (b)

major difference from the Guard-Stage-Milestone approach, which may be considered its precursor. In the new standard, the collection of data related to the case is found in a case file, which is accessible by all the tasks. However, the data flow related to the tasks is not evident from the model. In the process examined in this article, the case is a conference but several tasks operate on papers; therefore showing the connections between business entities and tasks will improve the understanding of the model. For this reason, a more articulated view of the case data may be advisable: this could be a relevant direction of development.

CONCLUSION

Business processes address complex systems resulting from the integration of several aspects, i.e., activities, roles, business entities, control flow rules and data flow rules. For this reason, a single model might be too complex and then its decomposition driven by specific viewpoints may help improve its readability and understanding.

The major contribution of this article has been to illustrate the key modeling issues of business processes and to present three forms of representation. In the first one, i.e., the global model, all the tasks appear in the same model; in the others, they

are distributed on the basis of two criteria: the entity life cycles and the roles associated with the tasks. These three forms address the dynamics aspects of the process and rely on a common information model providing the attributes and relationships of the business entities involved in the process. Current work is dedicated to the formalization of the iBPN notation and to the implementation of a suitable process engine.

KEY TERMS AND DEFINITIONS

Business Process: A standard way of organizing work in a business context. It consists of a number of process actions to be performed by a process engine.

Case Management: A flexible approach for taking care of a subject in order to achieve a desired outcome. The actions cannot be anticipated in a predefined sequence of tasks: the case workers

may perform the run-time planning of the tasks to be carried out.

Data Flow: The information items used and produced by the tasks.

Data Selection: A situation in which a performer has to select the input data before performing the task.

Performer: For a given task, the user in charge of performing it.

Task Selection: A situation in which a performer may operate on the same input data with a number of alternative tasks.

Task: A unit of work in the system.

Serious Games in Entrepreneurship Education

Fernando Almeida

Polytechnic Institute of Gaya, Portugal

Jorge Simões

ISPGaya, Portugal

INTRODUCTION

Computer games are currently often used in different serious applications and especially in the terms of vocational education and training. In fact, serious games (SG) are used in a wide variety of areas, in several aspects of common life, such as for health, politics, advertising, project management, and virtual reality, amongst others. The intention of serious games is based on the idea to offer a balanced possibility for an authentic and amusing learning. Currently the teaching community is progressively discovering how game based learning supports the personalized trainings and gives new instruments for teaching basic key competences.

At the same time, one of the main challenges of educational programmes is to ensure that education delivers the right skills for the labor market and the growth of entrepreneurship, while delivering support to young people to secure their economic future and enable businesses to grow and create new jobs. Actually, entrepreneurship is considered as the most common powerful economic force across the globe (Gwija et al., 2014). Entrepreneurship education has the capability to benefit students from all socioeconomic backgrounds because it guides students to think outside the box and nurtures unconventional talents and skills. Furthermore, it fosters innovation, ensures social justice, encourages confidence and stimulates the economy.

Serious games may be considered powerful tools to sustain entrepreneurship in the context of the emerging paradigm of Technology Enhanced Learning (TEL). Serious games combine simultaneously instruction and gameplay, by challenging and involving players in motivating learning contexts. They also offer students a genuine “situated” learning experience and can concretely support the “learning by doing” approach, considering that simulations offer a more pragmatic experience and provide a safe environment in which immersive entrepreneurs could test their own business.

This study aims to identify and synthesize the main key benefits, but also challenges and issues, provided by the introduction of serious games in the learning process. For that, we initially perform a revision of literature in the field of simulations and serious games initiatives applied to entrepreneurship domain. In this context we briefly present and describe five serious games initiatives in entrepreneurship education. After that, we identified and discussed the main key benefits and challenges created by the introduction of serious games. Finally, we look for current and emergent future research directions and we draw the conclusions of our work.

BACKGROUND

According to Belloti et al. (2014), entrepreneurship is “a personal skill and motivation which

draws a person to engage his abilities and efforts in the creation of new products and services". The European Commission defines entrepreneurship as "an individual's creative capacity, independently or within an organization, to identify an opportunity and to pursue it in order to produce new value or economic success" (Carvalho et al., 2012). Entrepreneurship education is often seen as a way to foster economic growth and to deal with economic crisis (Allegra, 2013). However, entrepreneurship education is often pointed as immature, not sufficiently integrated in schools curricula and not adequately addressed by national policies, particularly in European countries (Allegra et al., 2013; Belloti et al., 2014).

Today, digital technologies are part of most people lives, from the early childhood. Educators and corporate trainers did not ignore this reality and Information and Communication Technologies (ICT) are being used in education and training for several years with different approaches, including the use of games. Games have been used for a long time (Farber, 2015; Schifter, 2013) as a support for learning activities. In the last decades, the popularity of video games and the introduction of ICT in education and training gave rise to a trend known as Game-Based Learning (GBL). This trend deals with games that have defined learning outcomes. Within GBL, simulations and serious games have gained notoriety (Allegra et al. 2013; Bastos et al. 2012).

According to Kapp et al. (2014), simulations provide a cost-effective scenario for training tasks that would be costly and time intensive to set up in a real scenario. Simulations must be realistic, they should allow to practice behaviors and experience the impact of decisions. Simulations provide a safe and realistic environment to test and get feedback of those decisions.

SGs is a term usually used to designate games with educational purposes. The term was coined by Clark Abt who published the book "Serious Games" in 1970 (Farber, 2015). Abt, cited by Ulicsak & Wright (2010), defined serious games as games that "have an explicit and care-

fully thought-out educational purpose and are not intended to be played primarily for amusement. This does not mean that serious games are not, or should not be, entertaining". Other definitions can be found as the one proposed by Laamarti et al. (2014) which state that "serious game has the potential to enhance the user's experience through multimodal interaction. This can be in different contexts such as education, training, health, or interpersonal communication". In this definition a SG can be seen as an application composed by three components: experience, entertainment, and multimedia (Laamarti et al., 2014).

Simulations and serious games share common features (Kapp et al., 2014) and they often overlap. They both have story line, they can be competitive and they can keep some kind of score. But while games may not reflect reality, simulations must be realistic representations of the real world. Serious games in particular have been considered as powerful tools to support entrepreneurship education (Belloti et al., 2014; Bastos, 2012). Belloti et al. presented a comprehensive study with an overview of several serious games available and identified some key benefits regarding their adoption in entrepreneurship education. Some of the studied games were Hot Shot Business, SimVenture and Go Venture Any Business, detailed below, and used in three higher education case studies (Hauge et al., 2013).

To introduce students with the basic principles of entrepreneurship, Hot Shot Business¹, a Flash game, allows students to open and run a simulated business and undertake the necessary actions to make it grow. Currently, users can choose to run a pet spa, a custom skate factory or a comic shop. Target users are teenager students but the game can also be used in higher education contexts. The game is a cartoon-like simulation, easy to use, available through a web browser with a high game speed suited for young users. Users choose the financing mode of their business, the resources they need and how to advertise the business. They get feedback through simple weekly financial reports to tune their activities and decisions. Hot

Shot Business was successfully employed to teach the basic principles of entrepreneurship (Hauge et al., 2013).

SimVenture² is a detailed single player simulation of a small computer assembly and selling company and aims university students and professionals. Users receive feedback in the simulation's monthly cycles and the all session runs for one simulated year. During the session bankruptcy may occur causing an early end of the game session. The game provides to the users several indicators for self-assessment and exports data to a spreadsheet allowing for students' comparison.

GoVenture Any Business³ is another business simulation platform that can be used with different types of businesses, industries and markets. Players can compete with other players or with the computer to successfully manage a business. Players have to make business decisions by setting different parameters (e.g. price, product features, and human resources) before the end of each simulation. The game presents the results of the students' actions in terms of sales and profits. An instructor receives detailed reports with all the students' actions.

Another online serious game for entrepreneurship is the ENTREplorer⁴ project (Carvalho et al., 2012) an European funded project. The project aims to improve training activities and initiatives for young entrepreneurs willing to run their own businesses. The game assists students to acquire entrepreneurial skills simulating the environment where they will develop real work. The game platform is also web-based and multiplayer. Players go through different scenarios or levels (represented as floors in a building) where they learn different subjects and face challenges. In each floor players learn about the phases of creating a new business. The game guides players through the different phases in the process of writing a business plan.

PNPVillage⁵ (Allegrò et al., 2013) is also a web-based serious game developed under an European project focused in fostering, especially among youths, the entrepreneurial mindsets. PNPVillage, where students have to manage a tourist resort,

creates a simulated environment to help students deal with complex situations and encourage competition among them. The game is level-based and students can progress from simple scenarios to more complex ones dealing with the main issues of company management. The game engine was integrated in a Learning Management System in order to improve the benefits of both platforms.

Although the above examples and others are already in use, there are still many difficulties in using video games for educational purposes, from both teachers and students: "bringing effective games to students has many barriers. Teachers may see play as frivolous, while students may be biased against learning games in school" (Farber, 2015). Also, the entertainment quality of many serious games is often quite low, particularly when compared to commercial games (Belloti, 2014). Games require "a large amount of design and development efforts" (Dicheva et al., 2015) and, therefore, "creating a highly engaging, full-blown instructional game however is difficult, time consuming, and costly" (Kapp, 2012). Regarding entrepreneurship education, the study from Belloti et al. (2014) pointed that most of the games focus only on company management with lack of support for improving specific entrepreneurial mindset. This mindset includes fostering the students' creative and innovative potential and must also improve their autonomy (Allegra et al., 2013).

DISCUSSION

The adoption of serious games in the learning process offers many key benefits for students and teachers but, simultaneously, brings also some challenges and issues that should be properly analyzed and mitigated in order to offer a complete immersive experience.

Key Benefits

GBLs help students to understand more easily concepts and remember them in a seamless way.

Sitzmann & Ely (2010) in a meta-analysis found that learners participating in simulation game learning experiences have 11% higher declarative knowledge, 14% higher procedural knowledge and 9% higher retention of training material than those trainees participating in more traditional learning experiences. Additionally, immersion in a learning environment can be highly realistic. It is expected that an entrepreneur that gets an experience by playing serious games with real life situations of business, will be able to overcome the problems by recollecting the solutions he learned from the game (Kapp, 2010). This approach is adopted by SimVenture and GoVenture SGs where players have to make business contextualized decisions. According to Gopal et al. (2015) serious games should also give the visualization effects and experience on different problems and solutions, which will affect the cognitive mind of the player. This situation will help the player while he/she is facing similar situations in real business.

Serious games in entrepreneurship education provide typically different scenarios, situations, problems and their solutions in a business environment. Therefore they can be used to analyze the global environment with the intent to identify international entrepreneurship opportunities. Typically after completing levels and scenarios of the games, the player will get an idea about the common challenges and their solutions in the business field. Typically a common difficulty faced by students when trying to create a new business is around the concept of financial viability. There are traditional difficulties to understand the concept of cash flow and its impact in the business. Serious games can be used to more easily understand, categorized and apply in practice this concept. This approach is fully adopted by PNPVillage SG where the player progresses from simple scenarios to more complex ones, while managing and self-monitoring market trends, financial indicators and cash flow projections.

Game enjoyment by students has been shown to be an essential factor in the learning process (McClarty et al., 2012). Identification with fictional

characters has been researched during these last years and has been found to be one of the main factors why people enjoy the use of different media (Looy et al., 2010). Therefore, the role of avatar identification in the learning experience of a serious game is particularly relevant. Furthermore, Ahn et al. (2014) have confirmed that an experience as an avatar can change a person's real life perceptions and behaviors. Several serious games capture players and provide immersive experiences through the use of avatars. A good example of this approach is done by Hot Shot Business SG, where the player takes on the role of pet spa manager, skate factory owner or a comic shop manager. In such games, players either inherit a strongly formed and appealing character or they get to build a character from the ground up. Therefore, players become committed to the new virtual world in which they will learn and act.

Serious games also allow students to work together to accomplish tasks and goals as a virtual team. In cooperation, students can split the work, solve sub-tasks individually and then assemble the partial results into the final output. This possibility is highly suitable for entrepreneurship context where multidisciplinary competencies are fundamental. Fayolle (2007) & Wilson (2008) confirm this theory by advocating that teaching entrepreneurship requires a multidimensional and cross-disciplinary approach with an emphasis on dynamic processes. Additionally, entrepreneurship classes attract a significant number of student workers, which typically have less availability to attend the semester sessions. In this way, serious games can be used to promote greater collaboration and cooperation between students and teachers, while they are at home or at work.

Most serious games are role-playing games (RPGs), which means that users adopt the role of "invisible actors" who take actions based on the decisions of the person playing the game. A key element in this approach is the construction of an immersive story composed by different characters, scenes and a narrative. Lippa & Borst (2013) advocate that the human brain has a natural affinity

for narrative construction and that people tend to remember facts more accurately if they encounter them in a story rather than in a list.

The key benefits found can be systematized in five elements:

1. Facilitate the learning process by turning it more realistic and attractive,
2. Test different scenarios, situations and problems in business context,
3. Game enjoyment,
4. Virtual cooperation, and
5. Immersive experience.

Challenges and Issues

One of the major concerns identified about using GBL approaches in classrooms is the difficulty in assessing effectiveness at achieving the learning goals. Additionally, the adoption of serious games in academic context can interfere with evaluative learning and creates an additional increase difficulty in evaluating individual learning when teams play. The assessment process should take into account all the classroom or focus group and not only assess an individual player performance. This is considering a crucial element in entrepreneurship classes, where students need to work in group and establish a high degree of cooperation among them. Some serious games offer explicit scoring mechanisms that can be used to determine the performance of the player, namely the number of correct answers or time taken to complete a game. This approach is implemented by ENTRExplorer game, where the score of the user is calculated based in the number of correct answers provided by the players. The appropriate assessment methodology is also dependent upon content and context. Ulicsak (2010) states that the game play may have more of an impact on learning as that determines how feedback is given.

Kirriemuir (2010) has shown that it is difficult for teachers and other school stakeholders to easily realize the full potential benefits of serious games. Researchers found that teachers

have shown difficulties to identify quickly how a particular game is relevant to some component of the statutory curriculum, which includes also the entrepreneurship area, as well as the accuracy and appropriateness of the content within the game. Egenheldt-Nielsen (2011) states that the most important consideration from a teacher's perspective is how much the game will make their life easier. Thus it involves to analyze how the selected game will easily enhance teaching, or, if there is not yet a relevant game in that area, what a game would need in order for it to be useful. Furthermore, the lack of time available for teachers to familiarize themselves with the games, and methods of producing the best results from its use have been reported as a constraint. Schools can achieve this challenge by reserving some amount of time in the final semester for teachers' coaching, where teachers can discuss about their practice in classroom.

Serious games have to be embedded in a didactical system. In entrepreneurship domain the challenge is even bigger due to its inter-disciplinary approach. Therefore, schools and programme coordinators need to guarantee that students acquire knowledge from different disciplines through a unique theme. At the end, teachers should always care and make a critical analysis about what went good or wrong with the introduction of a serious games in the classroom. A key challenge in this process is to assure that players are engaged and motivated with the game. Having fun is central to effective learning. According to Karner and Härtel (2011) the goal is to enhance a self-reflexive attitude, because through individual reflexion self-controlled learning will be successful.

In order to offer an immersive experience serious games needs to support different styles of learning. The background heterogeneity of students that typically are enrolled in Entrepreneurship classes increases the creativity and potential of new business ideas, but turns more difficult to define a well stable learning approach. For instance, there are students that prefer visual styles, but others are more auditory. In fact, it

is a challenge to combine and support different types of media elements, such as text, pictures, videos, audio, and different types of communication. Each student will have its own experience of gaming and learns in a different way. This has to be recognized through the phase of conception and planning the game (Karner & Härtel, 2011).

Finally, there are also interoperability, accessibility and usability issues (Gooriah, 2013). There are two main factors involved in interoperability of serious games: content identification (e.g. integration with a Learning Management System such as Moodle) and data exchange (e.g. access to questions and test data results). Accessibility and usability issues are also common due to the nature of a serious game, that typically have a huge dynamic situations and offer great interactivity, turns very difficult to achieve high levels of accessibility and usability compliance.

The main challenges and issues can be summarized in five dimensions:

1. Difficulties to assess the effectiveness of learning goals,
2. Realize the full potential benefits of serious games by teachers and school stakeholders,
3. Embedment in a didactical system,
4. Support different styles of learning, and
5. Interoperability, accessibility and usability issues.

FUTURE RESEARCH DIRECTIONS

There are several perspectives about future evolution of serious games. In our work we will look mainly for the challenges that affect the entrepreneurship learning and behavior of the students regarding the idea to build their own business.

A first research direction that we can appoint concerns the assumed motivational impact of games, particularly the relation between “flow” and learning from serious games. Flow has been described as such an extent of involvement in a

task that nothing else seems to matter (Arnab et al., 2012). According to Wouters et al. (2013) it is undeniable that players fully engage in popular games and forget the real world around them, it is still unclear how such full engagement relates to learning. With this focus research may begin to establish links between game features, motivational processes, and learning outcomes.

Another perspective for future research concerns the validity and relevance of the learning outcomes. The use of traditional assessment methods with the adoption of future games still deserve deeper research. Additionally, assessment methods should take the context of learning into account and, therefore, it can evolve from traditional evaluation methods for more innovative assessment models that could reflect better the dynamics created by the students working groups.

The entrepreneurship education is interdisciplinary in nature. This situation turns entrepreneurship so exciting but also creates additional challenges for teachers and students. Students, for example, need to learn a wide set of different competencies from disciplines such as design, finance, technology and engineering. Additionally, students need to interact in multidisciplinary groups and accept the different of knowledge and personal behavior of several students. On the other hand, teachers have the challenge to be particularly attentive and solicitous to all students from different disciplines. In addition to that, there is a rapidly changing technology, human mindset, social value, business and personal values, entrepreneurship as a career path looks different and feels different (Neck & Greene, 2011). Connor et al. (2014) defend that in order to accommodate all new waves in the global environment there is a need for a framework of teaching.

Finally, there is a need for the establishment of new innovation policies that could stimulate stronger links between academia, business and entrepreneurs. For that, the technology transfer offices of universities and polytechnic institutes should have a more active role and establish

cooperation between teachers and students that could facilitate the appearance of new spinouts from academic institutions.

CONCLUSION

Serious games offer the potential of improving learning processes by providing attractive, motivating and effective tools that may also create positive situations among students and with teachers. Serious games create the ideal model to match the content in different ways and incorporate problem-solving and reasoning stimulations, which results in learning core competencies.

Serious games can be used in different academic contexts and, definitely, entrepreneurship education is an important challenge for the nowadays knowledge societies. Entrepreneurship education requires practices that make it possible to unleash the creative and innovative potential of young people, enabling them to work with multidisciplinary teams and contexts, while they create their own jobs and promote a more dynamic economy. When adopting serious games, students are motivated and guided more efficiently and effectively in the management of their virtual companies, receiving the necessary information regarding entrepreneurship, management principles, marketing research and financial analysis.

The introduction of serious games for entrepreneurship education offers a wide range of key benefits, namely in terms of students' motivation, immersive experience, and acquisition of multidisciplinary competencies. Additionally, serious games offers an environment that promotes the free choice of learning place and speed, flexible time-management and autonomous learning in the game context. However, the adoption of serious games for entrepreneurship education brings some challenges and issues that should be properly mitigated by educators. Among them, we highlighted in our study the difficulty in assessing effectiveness at achieving the learning goals, the need for

embedded in a coherent didactical system, support different styles of learning, interoperability of serious games in terms of content identification and data exchange, and accessibility and usability of the serious games platform.

KEY TERMS AND DEFINITIONS

Entrepreneurship: The capacity and willingness to develop, organize and manage a business venture along with any of its risks in order to make a profit. The most obvious example of entrepreneurship is the starting of new businesses.

Flash: A popular authoring software developed by Macromedia that is used to create vector graphics based animation programs with full-screen navigation interfaces.

Learning Management System: A software system that delivers courseware plus e-tutoring over the Internet. It is typically also called as Course Management System, Pedagogical Platform or E-Learning Platform.

Role-Playing Games: A game in which the player assumes the role of a character, generally in a fantasy or science fiction setting, that can interact within the game's imaginary world.

Serious Games: A game designed for any purpose rather than entertainment.

Simulations: A simulation game assumes typically a form of video or computer game that is concerned with playing out realistic situations in game settings.

Technology Enhanced Learning: The adoption of technology in order to promote a better classroom experience for students or increase e-learning pedagogic activities.

Architectural Framework for the Implementation of Information Technology Governance in Organisations

Thami Batyashe

Cape Peninsula University of Technology, South Africa

Tiko Iyamu

Cape Peninsula University of Technology, South Africa

INTRODUCTION

For many organisations, it is not just about information technology (IT), but about governance of systems and technologies, which is inseparable from people and processes. In a similar manner, as business management is governed by generally accepted principled practices, IT must be governed by practices that facilitate and make sure an organisation's IT resources are used responsibly and that its risks are managed appropriately. According to Van Grembergen and De Haes (2007), the widespread application of technology has generated a critical reliance on IT, necessitating a special focus on IT governance. The past decade has seen the term 'governance' moved to the forefront of business thinking in response to instances indicating the importance of good governance of IT. Governance is not an approach by itself, it is guided by architecture.

Enterprise architecture (EA) consists of four main domains, business, information, technical and application (Iyamu, 2014). Technical architecture means IT architecture in the context of this paper. This paper focuses on the technical architecture in the context IT governance. Technical architecture involves the design of systems or sets of systems. Iyamu (2011) defined technical architecture as a logically constant array of prin-

ciples, standards and models that are originating from business requirements. It guides the engineering of an organisation's information systems and technology infrastructure across. According to The Open Group Architecture Forum's (TOGAF) document of 2009, IT architecture provides some governance aspects, such as change management and quality assurance. In other words, it is the grouping of systems, represented in components, their relationships to each other and the environment, and the principles governing design and development.

IT architecture is driven by the need to bridge the gap between IT and business people and process towards a common goal of the organisation. Klein and Gagliardi (2010) describe IT architecture as "the logical software and hardware capabilities that are required to support the deployment of business, data and application services. This includes IT infrastructure, middleware, networks, communications, processing and standards". Along the same vein, in 2009, TOGAF described IT architecture as the hardware, software and network infrastructure needed to support the deployment of core, mission critical applications of an organisation. These activities require management and governance in achieving the objectives as well as a return on investment (ROI) for the organisational purposes.

BACKGROUND: IT GOVERNANCE AND ARCHITECTURE

Some organisations view both IT governance and architecture from two different perspectives, in implementation and operationalisation. The main and most commonly adopted IT governance frameworks include COBIT, ITIL, ISO/IEC 17799/27002 and TOGAF (Simonsson & Johnson, 2006; Niemann, Eckert, Repp & Steinmetz, 2008). Enterprise architecture (EA) is the focal point, though some organisations do sometimes focus on one or two domains of EA.

Mårten, Lagerström and Johnson (2008) asserted that the aim of IT governance is to support IT's function as a business enabler in order to realise the internal effectiveness in an organisation. IT governance enables and improves IT and business strategies gain alignment, including management of risks. Brown (2006) argued that IT governance governs the crafting and execution of the IT strategy, and also help to aligns both IT and business strategies.

The IT Governance Institute (2007) defined IT governance as the “responsibility of executives and the board of directors, and consists of the leadership, organisational structures and processes that ensure that the organisation's IT sustains and extends its strategies and objectives”. Concurring, Ross, Weill and Robertson (2006) refer to IT governance as “the decision rights and accountability framework for encouraging desirable behaviour in the use of IT”. IT governance focuses on managing and employing IT to realise corporate performance objectives whilst reflecting the wider corporate governance principles.

Enterprise architecture (EA) is intended to govern and manage both technical and nontechnical activities of an organisation. According to Anaya and Ortiz (2005), “an Enterprise Architecture provides a common view of the primary resources of any enterprise (people, processes and technology) and how they integrate to provide the primary drivers of the enterprise (that is, the strategy)”. Enterprise Architecture can be used to guide

against business-IT misalignments. This includes coordination of technology investments, to suite business needs, improve the integration between services, and eliminate redundant investments while replacing them with standardised and cost effective IT services. Becker, Antunes, Barateiro, Vieira and Borbinha (2011) stated the purpose of EA is to provide a comprehensive coverage of the organisation.

Weill and Woodman (2002) asserted that IT architecture offers an interrelated set of technical choices to direct the organisation in sustaining business needs. According to Hafner and Winter (2008), IT architecture is the sphere of architecture which signifies a combined, enterprise wide model of hardware and communications elements in addition provides support among the technology artefacts. While Iyamu (2011) maintained that it guides the initiation of new technology. IT architecture as defined by Weill and Woodman (2002) is a set of procedures and guidelines that govern the use of IT and design a migration path to the way business will be done. IT architecture consists of standards and guidelines for technology, utilisation of data, design of applications and change management processes necessary to use new technologies.

RESEARCH APPROACH

The qualitative, case study and interpretive methods and approach were followed in conducting this research, which was to develop an architectural framework for the implementation of IT governance in the organisations. Qualitative research methods assist researchers to understand people and the social and cultural contexts within which they live. Concurring, Denzin and Lincoln (2011) asserted that qualitative research is often based upon interpretivism, constructivism and inductivism. It is about exploring the subjective meanings through which people interpret the world and the diverse ways in which life is constructed in particular settings. Social events and phenomena

are understood from the perspective of the people themselves, thus avoiding the imposition of the researcher's own presumptions and definitions.

The case study research approach was followed in this study. A South African organisation, RedLeaf Communications was used as the case, with specific focus on the IT division of the company. Case studies are empirical studies that investigate a contemporary phenomenon within its real life context using multiple sources of evidence (Yin, 2003). Noor (2008) sees case studies as being concerned with “*how*” and “*why*” things happen, allowing the study of appropriate realities and the differences between what was planned and what actually occurred. Thus case studies are a valuable approach of looking at the world around us. Willis (2007) defined a case study as “an examination of a specific phenomenon such as a program, and event, a person, a process, an institution, or a social group”. The case study approach, according to Creswell (2007) “explores a single entity or phenomenon bounded by time and activity and collects detailed information by using a variety of data collection procedures during a set period of time”.

The semi-structured interview approach was employed to collect data. This is mainly because the approach allows the interviewer or interviewee to deviate in order to pursue an idea or response in more detail (Rabinet, 2011). According to Qu and Dumay (2011), the semi-structured interviewee approach helps to reveal important and often hidden aspects of human and organisational behaviour. Kvale and Brinkmann (2009) argued that it is often the most effective and suitable method to collect data.

The hermeneutics method, from the perspective of interpretivism, was employed to analyse the data, in order to make sense of the subjective views and opinions of the participants in this study. Hermeneutics is constantly employed within interpretive research. Hermeneutics is the discovery or discipline of interpretation. Its primary concern is questioning the meaning of a text or text-analogue, which can be a book, scholarly

article, interview notes or an organisation (Myers, 2009). The hermeneutics practice states that in qualitative research, the interpretation is mainly used, no matter how adamantly many researchers may argue the facts speak for themselves (Folwer, Horan and Cope, 2007). These researchers further stated that hermeneutics is a form of interpretive research where researchers begin with the assumption that interaction to our understanding of reality is gained only through social constructions such as language, consciousness, shared meanings, documents, tools and other artefacts. In Information Systems (IS), interpretive research is aimed at creating an understanding of the context of IS and the process by which IS affects and is affected by its context (Fowler, Horan and Cope, 2007).

ARCHITECTURAL FRAMEWORK FOR THE IMPLEMENTATION OF IT GOVERNANCE

The data was collected from the case study, RedLeaf Communications was analysed. The analysis was carried within the context in which data was gathered: (1) What are the factors that influence the selection of IT governance in the organisations? (2) How is IT governance implemented in the organisations? The findings from the case study were combined and presented in Figure 1 below to give a better understanding of the common factors which could influence the implementation of IT governance in organisations.

The critical factors found at RedLeaf Communications, were evaluation of information, technology repository, education and training, organisational strategy and organisational culture. Also found were factors which include environmental assessment, training, knowledge sharing, communicative scheme and organisational culture. The combination of the findings informed the development of the Architectural Framework for IT Governance (AFITG), which can serve as a best practice guide to the implementers of IT governance frameworks in organisations. The

Figure 1. Architectural framework for IT governance (AFITG)

framework (AFITG) is considered a best practice mainly because of the depth and rigour through which empirical evidence was examined, and its organisational relevance.

It is believed that this study could be generalised for the benefit of organisations as the commonalities in the findings from the case. According to Walsham (1995), a generalisation can be made to a concept or a theory can be developed or generated from facts or a rich description of a case. Lee and Baskerville (2003) asserted that generalisation is important for the purposes of managing and solving problems that corporations and other organisations experience in society. Along the same line of argument, Qureshi, (2005) posited that the insights from a case study can be generalised to reach conclusive or theoretical statements for other organisations' purposes.

The framework in Figure 1 depicts four fundamental categories in an organisation that must work in concert for the implementation of IT governance to be effective: organisational needs, managing, assessment and innovation. Figure 1 suggests that if a change in IT governance is made in an organisation such as the introduction of a

new governance framework, this change is likely to affect the other three categories. For example, changes in organisation needs can lead to managing changes, and organisation needs can drive changes in innovation.

Implementation of IT Governance Frameworks

Figure 1 illustrates the most critical factors which impact and influence the implementation of IT governance frameworks. These factors are categorised into organisational needs, innovation, assessment, and managing. Each category relates to each other and no category stands on its own. Also, each category positively supports the others. The factors are considered critical because of their prevailing and significant roles, as shown in the analysis of the case study. The categories are discussed in more detail below.

Organisational Needs

Organisational needs are made up of strategy, structure, culture and alignment. IT strategy is

informed by and aligned to the organisational strategy. An IT structure must support the IT strategy to ensure the organisation's objectives are achieved. An organisational culture is shaped by the norms and values of the organisation and the management and individual practices.

- **Strategy:** To change its operations, an organisation's IT management needs to define a strategy that is aligned with the organisational and business units' strategies. It needs to become a true service provider that operates like a business within a business; the IT strategy should entail an IT governance framework that fully involves the organisation's management and individuals in planning and aligning IT initiatives with the organisation's priorities. Once the strategy is operational, the structure that supports the strategy should be outlined and implemented with the support of the organisation's management.
- **Structure:** Structure is extremely important and a key element in implementing an IT governance framework. The role of the structure within the organisation is to define expectations, assign responsibilities and verify performance. This structure also establishes the strategic, operational and technical decision-making processes, which are critical. This helps to manage IT investment; assign trained and capable resources to govern IT resources; put appropriate standards, principles, and policies into place; and create the disciplines around governing and managing IT artefacts. Similar to any major organisational innovation, implementation of IT governance must have an owner and accountabilities. Putting the right IT structure in place is important to support and manage the implementation of IT governance usually requires having an organisational culture that embraces and supports innovation.
- **Culture:** Culture relates to the beliefs and values of the organisation, which are generally expressed in its mission statement, and these include ethical concerns. Management need to understand the influence culture has on the organisation's values and behaviours. A strong organisational culture fosters organisational learning capacity to increase awareness of how culture shapes organisational effectiveness by training and educating employees and creating communication programs to address critical cultural weaknesses.
- **Alignment:** Strategic alignment involves making certain that the business and IT plans are connected, and that IT operations are aligned with overall business operations. Alignment is a key element that, if ignored, can lead to serious management issues, sub-standard performance, and even financial problems. Alignment is not easy to achieve. The challenges of creating internal alignment of systems that support appropriate levels of risk-taking include the development of a common language, and an understanding among employees as to the nature and tasks of IT governance. Proper alignment also requires conflicts between functions be addressed. Unnecessary overlaps of jobs and areas of accountability, structure, as well as gaps in responsibility, must be identified and resolved. This may require complex and difficult organisational change.

Innovation

Organisations are continuously challenged to ensure the survival and wellness of their competitiveness and sustainability. Thus, there is a need for continuous innovation. Innovation is intended to provide improved approaches for efficiency and effectiveness in achieving an organisation's needs. There are three main factors which repre-

sent innovation. They comprise of information, systems and technologies. Information should facilitate making decisions regarding the systems and technologies that are required to implement the innovation.

- **Information:** Information is about the know-how and know-what of the organisation's decisions that needs to be made. Information assists decision makers to have an understanding of what needs to be prioritised to ensure that the right systems are implemented to achieve the goals and objectives of the organisation. It is also important to ensure that the relevant information is communicated to the relevant stakeholders.
- **Systems:** Although there are various definitions of systems, in this context system refer to the collections of technical and non-technical factors that enable an organisation to meet its desired objectives. A system which creates a cohesive work environment, and ensures that implementation of IT governance is understood and adhered to. Technologies are required to enable these systems.
- **Technologies:** Key technologies should be identified to automate and standardise those systems. It should then consider what linking technologies, if any, can be shared across the organisation. Organisations dependence on technologies is swiftly and continuously increasing. It is, therefore vital to ensure that IT capability is described and directed by the organisation's needs.

Assessment

An environment assessment can be conducted to identify IT objectives and to ensure that the business objectives are aligned with an understanding of management's risk appetite and understanding

of the maturity of the existing governance and related processes.

Assessment of the organisation environment assists management to identify the gaps in standards, principles, policies. Once they have been reviewed, new business proposals are provided to advice on IT governance compliance issues. As a result, policies are established to ensure compliance with relevant legislation. Policies that govern IT governance and the implementation and management of IT governance frameworks should be familiar with the relevant standards and frameworks and the principles embedded within them.

- **Standards:** standards are set to ensure uniformity of systems, processes and technologies. However, standards, principles and policies are not permanent solutions as their effectiveness depends on how they have been implemented and kept up to date. Standards are highly valuable when they are used as a set of principles to begin the customisation of certain policies. It is therefore important for management and employees to understand what to do, how to do it, and why it is important.
- **Principles:** the organisation needs to provide the direction and guidance for the selection and implementation of IT governance based on the capacity and organisational strategy. The guidelines point the organisation to the principles that should be reinforced to manage IT governance. These principles are extremely useful to develop policies to manage and control IT governance.
- **Policies:** Policies for IT governance frameworks implementation include best practise framework and standards, stakeholder management, business alignment, knowledge transfer and management of the selected frameworks.

Managing

Managing the implementation of IT governance frameworks consists of three main factors: process, people and technology. The crucial job of implementing these IT governance frameworks is performed by people. All three factors are necessary to get a clear understanding of the IT governance processes, therefore these factors cannot be separated, as they rely on each on the success or failure of implementation IT governance frameworks.

- **Process:** Processes are used to guide the activities of people in the execution of various tasks. Also, processes are applied in the management (selection, implementation, and support) of information systems and technologies in achieving the organisational needs. Without processes, the organisations would face challenges achieving their objectives and managing day-to-day operations. The failure of most IT governance implementation is the lack of well-defined processes.
- **People:** The processes are developed by people, based on their understanding and know-how. People have an integral role in process. People make use of processes at their discretion, either for personal interest or organisational interest, in the selection, implementation and management of information systems and technologies. Different people have different skills and knowledge, which is required in innovations undertakings such as implementing IT governance. This makes their role a determining factor to the success or failure of the organisations' goals and objectives. Thus, it is important to involve the right people, doing the right things, in the right ways, at the right times.
- **Technology:** The implementation of IT governance frameworks can be complex and involves technology, process and

people at all levels of the organisation. Technologies are used to enable an organisation's goals and objectives. However, technologies can also constrain the organisation in the quest for competitiveness. Hence the use of technologies highly depends on its management by people, through processes.

Significance of the AFITG

The architectural framework described in the previous section guides organisations in the selection, implementation and management of frameworks for IT governance. It proposes a strategic plan for IT, which satisfies the current and ongoing needs of an organisation's business strategy, and the current and future IT capabilities. It promotes clear decision making, leading to valid reasons for IT acquisitions.

Also, the architectural framework monitors provision of IT services, levels of service and service quality. Thus, it assures that the organisation's business processes, people and technology are compliant with relevant IT governance legislation and that the organisation operates according to the principles embedded in relevant IT governance frameworks. The AFITG also promotes IT standards, principles and policies, and decisions that recognise the current and changing needs of organisations.

FUTURE RESEARCH

The study was methodically and comprehensively carried out within the objective, which was to develop an architectural framework for the implementation of IT governance in organisations. This includes understanding of the factors that influence the selection and implementation of IT governance in an organisation. The findings and analysis reveals that further work with different users and settings will support the research's understanding of the processes that are employed

to selecting, implementing and managing IT governance frameworks. In addition, such further research could make use of the framework that is presented in chapter as a point of departure, thereby explores its validity and practicality.

The analysis and interpretation of the two case studies uncovered participants' concern regarding factors, such as organisational culture and organisational strategy during the selection and implementation of IT governance frameworks. It would be in the interest of scholars to explore and gain a better understanding how organisational culture and strategy influence the selection and implementation of IT governance frameworks.

In addition, further studies could be conducted on the impact that training and educating the implementers and non-implementers has on the implementation and management of IT governance frameworks. Actors need to be knowledgeable on the selected frameworks of IT governance they implement in order for them to make better decisions to innovate.

CONCLUSION

Even though one organisation was used in the study, the framework can be generalised. This is mainly because there are many organisations that have similar challenges in the area of IT governance, as revealed in the study. Also, many other organisations that do not yet have challenges, but could potentially do so, now have the privilege of preventing them before they occur. As presented and discussed in this paper, the use of the AFITG brings a fresh perspective and helps with a deeper understanding of how IT governance can be selected and implemented, through its influencing factors in the organisations. The architectural framework, shown in Figure 1, which was derived from the study, illustrates how non-technical factors can influence and impact the implementation IT governance frameworks in organisations.

This study can assist boards of directors, top managers and other employees in organisations to better comprehend the factors which influences or can potentially impact the selection, implementation and management of IT governance frameworks in their organisations. Also, the study can be a useful material to the academics, in twofold: (1) It can be used as a case material, from empirical evidence perspective, and (2) the framework can be used as theoretical foundation.

KEY TERMS AND DEFINITIONS

COBIT: Control Objectives for Information and Related Technologies is a framework that focuses on IT management and governance.

Enterprise Architecture: Systematic approach for governance of organisational artefacts.

Framework: Layered structure, which consist of social-technical factors.

IT Governance: Approach for control and management of IT artefacts.

ITIL: Information Technology Infrastructure Library, is a set of practices that focuses on IT services.

RedLeaf Communications: A South African based organisation that was used in the study.

TOGAF: Open Group Architecture Forum's.

Continuous Assurance and the Use of Technology for Business Compliance

Rui Pedro Figueiredo Marques
Universidade de Aveiro, Portugal

INTRODUCTION

The concept of Continuous Assurance began to arouse much interest when in 1999 a joint committee of the AICPA (American Institute of Certified Public Accountants) and the CICA (Canadian Institute of Chartered Accountants) took up the issue of Continuous Assurance and defined it as a set of services and technologies which enables independent auditors to provide written assurance on a subject issued simultaneously with, or a short period of time after, the occurrence of events underlying the subject (Vasarhelyi, Alles & Williams, 2010). Nowadays, the concept of Continuous Assurance is still relevant due its contribution to the current organizational context, in which there is a fierce competitiveness and a constant need for more timely, relevant and reliable information to support the decision making and achieve the strategic and operational objectives.

In this context of constant change and increasing competitiveness, seeking productivity gains and improving management tools have been a core priority. Thus, Continuous Assurance has been asserting itself and assuming an increasingly important role within organizations, with the function of management support and, in general, to ensure the economic and efficient use of resources, areas where the effects of the impact of new risk factors caused by the constant change, fierce competition and widespread access to global information are more felt (Morais, 2008).

Continuous Assurance and Auditing are sometimes used interchangeably. However, assurance is a much broader concept than auditing because whilst auditing is a systematic process of obtaining

and evaluating evidences on organizational data and transactions in order to verify their compliance to standards, policies, or rules, assurance additionally includes professional services that ensure quality of information or its context, for decision makers (Soltani, 2007).

This chapter provides the concept of Continuous Assurance, its objectives and components, and a model which allows both to evaluate information systems with Continuous Assurance services and to help design the requirements of new ones. Finally, some implementations are also presented providing a comprehensive understanding the state-of-the-art and the benefits of Continuous Assurance.

BACKGROUND

Continuous Assurance is defined as the application of emerging information and communication technologies to the standard techniques of auditing, both mandatory periodic auditing and internal auditing. In that view, Continuous Assurance is a new step in the evolution of transactional auditing from manual techniques to automated methods. The term “continuous” does not mean real time, but to be effective considering, respecting and being consistent with the pulse and rhythm of each organizational transaction and process (Vasarhelyi *et al.*, 2010).

Furthermore, Continuous Assurance emerges as a set of services which aims to restore the credibility of auditing, simultaneously allowing organizations to meet the requirements of regulations. Hence, it can diagnose the company's

viability and allegations of fraud and illegal acts, assessing the economy, efficiency and effectiveness of organizations (Murcia, Souza & Borba, 2008; Vasarhelyi *et al.*, 2010).

In 2006, a survey (PricewaterhouseCoopers, 2006) concluded that Continuous Assurance triggered corporate sensitivity to its adoption because in 2005 only 35% had a continuous auditing or monitoring processes in place or were planning to develop one, and this value increased to 50% in 2006. It is interesting to observe that 56% of respondents said their continuous auditing processes include both manual and automated elements, 41% indicated their processes are entirely manual, and 3% reported having fully automated processes.

Another study by Institute of Internal Auditors and ACL (2006) also showed similar results: 36% of surveyed organizations confirmed they implemented a Continuous Assurance approach in all their business processes or simply in some selected areas, and 39% intended to implement in the near future. However, it also states that regardless of the reasons that organizations may have had to neglect the continuing auditing in the past, the recent regulations, the stimulus for real-time monitoring and reporting of financial information and the ability to automate the traditional audit methods have strongly encouraged its adoption.

The issues discussed regarding the motivations which are driving Continuous Assurance include: the growth of complexity and amount of data, the growth of electronic exchange of information and outsourcing, the integration of the value chain; reports available on the Web, and the users' desire for reliable information and disclosed more frequently, more timely and more detailed; and the need for disclosure of updated information imposed by the Sarbanes Oxley Act (section 409) (Brown, Wong & Baldwin, 2007).

Brown, Wong and Baldwin (2007) reviewed more than 60 articles on this topic and concluded that Continuous Assurance was still a concept for most organizations and a goal for the future. The implementation of systems with continuous assurance services was residual when comparing with

continuous monitoring and continuous auditing systems. These latter systems presented high levels of maturation regarding their implementation in the inquired organizations.

According to the section "Implementations" of this chapter, we can see that the implementations designated as providers of Continuous Assurance services, in the period 2002-2015, were still few and with some limitations regarding the diversity of services that Continuous Assurance should be expected to offer. This shows that this area is still developing and maturing.

CONCEPT

The concept of Continuous Assurance refers to the set of services which, by means of technology, uses the information immediately and produces audit results simultaneously with or within a short period of time after the occurrence of relevant events. Furthermore, it allows analytical monitoring of business processes. It is intended to be timely, more comprehensive, more accurate and more supportive to management than the traditional auditing (Alles, Kogan & Vasarhelyi, 2003, 2004; Vasarhelyi, Alles & Kogan, 2004).

Moreover, Continuous Assurance has provided a change in the auditing practice for the maximum possible degree of automation. Given the emphasis on the transformation of the entire auditing system, the development of Continuous Assurance requires a fundamental reassessment of all aspects of auditing, in particular on how data is made available to the auditor, how alerts are managed, what kind of reports are issued, and how often and to whom they are sent (Vasarhelyi *et al.*, 2010).

According to IFAC (2004), the subject matter, and subject matter information, of Continuous Assurance can take many forms, such as:

- Financial performance or conditions (for example, historical or prospective financial position, financial performance and cash

Figure 1. Continuous monitoring, auditing and assurance

Source: adapted from Coderre, 2005

flows) for which the subject matter information may be the recognition, measurement, presentation and disclosure represented in financial statements;

- Non-financial performance or conditions (for example, performance of an entity) for which the subject matter information may be a key indicator of efficiency and effectiveness;
- Physical characteristics (for example, capacity of a facility) for which the subject matter information may be a specifications document;
- Systems and processes (for example, an entity's internal control or IT system) for which the subject matter information may be an assertion about effectiveness; and
- Behavior (for example, corporate governance, compliance with regulation, human resources practices) for which the subject matter information may be a statement of compliance or a statement of effectiveness.

When Continuous Assurance services are running in real time, they provide the opportunity to manage transactions simultaneously with their execution or after a particular event, and even in some cases, the ability to interfere with the completion of the transaction, correcting it. When some service of Continuous Assurance points a wrong transaction, and this is corrected by the auditor, we can say the system becomes a proactive player in the processing of organizational information (Vasarhelyi *et al.*, 2004).

The terms Continuous Assurance, Continuous Auditing and Continuous Monitoring are sometimes used indiscriminately in literature. Therefore, it is crucial to understand what characterizes and distinguishes them, but mostly to understand how they can be relate to, complementing each other (Figure 1).

Continuous Assurance is a statement on the adequacy and effectiveness of controls and integrity of information. Continuous monitoring of controls is at the center of Continuous Assurance

strategies; however, the audit activity ensures that management activities are appropriate and effective so that organizations have a greater level of certainty about the effective operation of controls, about risk management and about the integrity of information used for decision making (Alles *et al.*, 2003; Coderre, 2005; Kuhn & Sutton, 2006).

In turn, Continuous Auditing refers to activities undertaken to provide warranty and credibility to operations, besides giving a more timely character to issues of control and management of risk. Continuous Monitoring is responsible for constantly monitoring and evaluating business transactions and their related controls, enabling a real-time view on effectiveness of controls and on integrity of transactions (Minnaar, Little & Farineau, 2008).

Evaluating the combined results of Continuous Monitoring and audit procedures, auditors can provide Continuous Assurance. However, only recently has an effort been made to understand their differences and distinguish between the concepts.

OBJECTIVES

The objectives of Continuous Assurance, making it really advantageous, are divided into four levels, which are difficult to define in a mutually exclusive way, but which serve to illustrate the functional dependence of Continuous Assurance on auditing (Vasarhelyi *et al.*, 2004).

Level 1: Evaluation of Organizational Transactions

At this level, it is intended to evaluate organizational transactions, and analyze and verify the atomic actions of transactions execution (for example, movement of money or information to the level of data that compose it). With the use of corporate systems, such as ERP (Enterprise Information System) systems, it is possible to analyze, aggregate and evaluate data in order to classify and monitor organizational transactions.

At this level, input data should be tested in order to verify whether they are valid, and whether procedures in execution of transaction are consistent with the sequence of established operations, for example check whether a certain movement in the stock corresponds to a sale, to a certain bill, and whether it is in accordance with the order received. Contrary to traditional auditing, with Continuous Assurance it is possible to do this check in real time due to automation and integration of audit procedures. This transaction control can use the formal specification of workflow of processes defined in the ERP systems as a standard behavior of transaction. Thus, it is possible to verify whether transactions have been executed in compliance with all provided steps to foresee the flow of transactions, and whether these are missing or failing.

Level 2: Compliance of Performed Operations

At this level it is intended to ensure that procedures applied in the execution of organizational transactions are appropriate (for example, are consistent with the rules, norms, or standards set by the organization or by external regulatory entities).

The procedures of this level use comparison with standards in order to verify the application of these rules and standards, and if any inconsistency is found, the situation will be forwarded to the auditors or other responsible person for consideration. Although in this latter case the resolution of the problem is not guaranteed in real time, this selectivity will allow greater efficiency in the auditors' tasks.

Level 3: Quality of Estimates and the Consistency of Aggregate Data

In some businesses, estimates and forecasts are often used because the measurement or direct determination of some information is difficult and expensive to obtain. For example, the percentage

of completion of a work is not always easy to measure, and therefore, must be estimated.

Even if an organization does not automatically generate an estimate, continuous assurance services can use their own formal models to ensure in real time that the estimate used is acceptable. Obviously, the creation of a formal model of an accounting estimate is not a simple proposition and can add significant costs to the development of Continuous Assurance. A simple and economical alternative is to use a formal model to automatically get an estimate, then the auditor's task will be reduced only to verifying the acceptability of this model, which can be done only once and off-line, based on knowing whether the used parameter values in model are reasonable.

This level of Continuous Assurance includes automation of analytical procedures based on internal and external parameters. The use of analytical procedures in an automated system of Continuous Assurance increases efficiency and effectiveness of auditing.

Level 4: Evaluation of Organizational Decisions

The auditing carried out by using ERP systems and advanced financial instruments must incorporate complex and high level assessments, which are especially important for decision making. Such judgments may have to deal, for example with the relevance of contingencies, the extent of related-party transactions, the boundaries of corporate systems, and the nature of the relationships across the value chain. Continuous Assurance and the current analytic technology allow the extensive gathering of exogenous evidence, which provides crucial input into these judgments. Continuous Assurance may use, for example data warehousing and data mining as tools that facilitate automation of some of these decisions, improving the quality of high-level decisions and decreasing the audit risk.

CONSTITUTION

Continuous Assurance is divided into three distinct components, but complementary (Vasarhelyi *et al.*, 2010):

- **Continuous Controls Monitoring (CCM):** Consists of a set of procedures to monitor the operation of internal control mechanisms;
- **Continuous Data Assurance (CDA):** Verifies the integrity of the data circulating in organizational information systems;
- **Continuous Risk Monitoring and Assessment (CRMA):** Measures the risk dynamically and allows to sustain an auditing plan.

Continuous Controls Monitoring

CCM is a set of emerging technologies which monitors controls in ERP systems and other applications in order to improve business governance, monitor and verify access and transactional rules, and to automate audit processes. CCM assists the business in: reducing business losses from fraud or failure; following rules or procedures which govern transactions; and improving performance through monitoring and auditing of the controls implemented in the systems (Caldwell & Proctor, 2010).

Caldwell and Proctor (2010) identified many important CCM functionalities, namely controls monitoring functions, exception and remediation management, reporting and analytics, and workflow. With these functionalities, CCM adds value, in an organization, to risk management and to the following compliance initiatives:

- **Lowering Compliance Costs:** CCM reduces the cost of auditing by eliminating some manual sampling and minimizing the time it takes to gather documentation;

- **Improving Financial Governance:** CCM can increase the reliability of transactional controls, improve auditor trust and increase the effectiveness of antifraud controls; and
- **Improving Operational Performance:** CCM controls, such as those that monitor duplicate payments, incorrect discounts or misapplied warranties, go beyond what most people consider compliance.

Continuous Data Assurance

CDA has been a powerful tool in organizations, particularly in financial and accounting areas, to extract data from organizational databases and applications in order to make analyses at the transactional level and to provide more detailed assurance. It has the main objective to change the traditional vision of data auditing in which reports were prepared and audited only once a year; sampling was used rather than examining the entire population; data were analyzed at the trial balance level using ratios.

This aggregation and analysis at a higher level than the transactional level has been a cost and capability-based limitation rather than the ideal process for assurance. Thus, CDA can continuously monitor transactions, comparing their characteristics with expected behaviors, thus identifying anomalous situations. When substantial divergences occur, alarms will be triggered and routed to the respective stakeholders (Vasarhelyi *et al.*, 2010).

To implement transaction verification it is necessary to specify data validity, consistency and referential integrity rules which are then used to filter data. These rules aim to detect and remove two types of data errors: data integrity violations (for example, invalid purchase quantities, receiving quantities and bank check numbers) and referential integrity violations which are largely caused by many unmatched records among different business processes (for example a payment made for a non-existent purchase order).

Continuous Risk Monitoring and Assessment

B

CRMA is the process by which organizations address the risks attaching to their activities in pursuit of organizational objectives and across the set of all their activities. Besides, CRMA involves: measuring risk factors continuously, integrating different risk scenarios into some quantitative framework, and providing inputs for audit planning, i.e. it engages risk assessment, risk evaluation, risk treatment and risk reporting. The organizational risk management approach is intended to align risk management with business strategy and embed a risk management culture into business transactions (Collier, Berry & Burke, 2007; Vasarhelyi *et al.*, 2010).

INFORMATION SYSTEMS WITH CONTINUOUS ASSURANCE SERVICES

Marques, Santos and Santos (2013) proposed a model composed of three dimensions and one requirement, which aims to evaluate an information system with Continuous Assurance services, and which intends to be regarded as a referential set of requirements when developing this type of information systems. The authors used the Delphi method to validate the model in order to ensure the relevance of inclusion of these dimensions and requirement and also a set of metrics to be included in each dimension and requirement (Marques, Santos & Santos, 2016). Furthermore, this model was successfully used in a more comprehensive research project (Marques, Santos & Santos, 2015).

It is composed of the dimensions Monitoring, Compliance, Estimation and the requirement Reporting, which comprise all objectives and components of a system with Continuous Assurance services (Marques *et al.*, 2013, 2016):

- Dimension ‘Monitoring’ relates with the objectives of level 1 and the component CCM. In this dimension, the following metrics may be found to assess whether the system can: monitor the various operations of a process as soon as they occur; identify an irregular (unforeseen or inconsistent) operation as soon as it occurs; verify whether the operations were processed at all the previous steps as required; detect lack of operations; and assess the continuity and completeness of transactions.
 - Dimension ‘Compliance’ includes the features of the component CDA and the objectives of level 2. The metrics associated to this dimension aims to assess whether the system can: recognize which known execution pattern was or has been followed by each organizational transaction monitored; ascertain which rules, conditions and procedures were fulfilled and unfulfilled in the organizational transactions monitored; detect potential errors; inhibit inappropriate events or behaviors; and help compliance with existing laws, policies, norms and procedures.
 - Dimension ‘Estimation’ covers the objectives of level 3 and the functions of the CRMA component. The metrics of this dimension assess whether the system can: estimate, given the current situation, what the possible results of the organizational transaction execution will be; and determine the execution pattern, or a set of execution patterns, which will be possible to be followed by the organizational transactions monitored, according to the current status of execution.
 - Requirement ‘Reporting’ includes the features of all components and the objectives of all levels. The metrics of this requirement must assess whether the system can: report the results of the monitoring of transactions; notify the results of the verification of compliance; inform the results of estimation; and alert users of irregular situations in monitoring, compliance verification and estimation of negative results.
- Table 1 concisely summarizes this model, presenting quantitatively measurable metrics for each dimension and requirement.

Table 1. Dimensions of the model and their metrics

Dimensions and Requirement	Metrics
Monitoring (dimension)	– Real-time monitoring of operations – Real-time identification of irregular operations – Real-time verification of processing of required operations at all previous steps – Real-time detection of lack of operations
Compliance (dimension)	– Recognition of execution patterns – Ascertaining of fulfilling of rules – Detection of potential errors – Verification of compliance of existing policies
Estimation (dimension)	– Estimation of possible results – Determination of possible execution patterns which are likely to be followed
Reporting (requirement)	– Real-time presentation of the executed operations which were monitored – Real-time presentation of execution patterns which are being followed or are likely to be followed – Real-time presentation of the compliance verification in transactions executions – Real-time presentation of the risk estimated on determining possible execution patterns – Real-time alert for irregular situations in monitoring, compliance verification and estimation of negative results

IMPLEMENTATIONS

Some solutions in the field of Continuous Assurance have been made available in the market and are mostly developed by well-established CAAT (Computer Assisted Auditing Techniques) manufacturers and vendors, which begin to position themselves in this still emerging market. Despite regarded as Continuous Assurance solutions by vendors, these products focus more on the CDA component. The implementation of CCM solutions is very complex due to significant differences in the types of business objects, process configurations and controls and then it is not cost-effective. Thus, these solutions have developed some very specific CCM modules targeted at specific enterprise systems. Such modules are quite laborious since they require customization for each new enterprise system (Vasarhelyi *et al.*, 2010).

An organization in the steel industry with 234 industrial and commercial units, present in 10 countries and with shares in New York Stock Exchange, was forced to implement measures of Continuous Assurance in accordance with SOX requirements. After these measures, all processes had to be documented and information started to be disclosed in time and with their integrity ensured and it held the participants responsible, inhibiting the occurrence of fraud (Hargadon & Fanelli, 2002).

Siemens has made an effort in this area and it has successfully experimented some aspects of Continuous Assurance, namely to ensure the integrity of its ERP systems and their automated modules with audit functions. Siemens's project proposes a methodology to monitor and evaluate the daily configuration of various settings of existing controls through the use of CCM, because about 68% of its audit activities could be fully automated. Thus, an independent system was developed for interacting with read-only operations with the existing information systems and for reporting system and alarms in case of emergency. These implementations have ensured the effectiveness, efficiency and a timely character

to the audit procedures. (Alles, Brennan, Kogan & Vasarhelyi, 2006; Alles, Kogan & Vasarhelyi, 2008). The use of CCM at Siemens Financial Services enabled significant improvements in the average exception rate, through the testing and monitoring of performance analytics (e.g. input checks, validity checks, and compliance with regulations and internal policies). In some departments, the reduction in the average exception rate was over 20% in the first year of implementation (Medinets, Gross, & Brennan, 2015).

Also according to Vasarhelyi *et al.* (2010), one of the biggest banks in Brazil, with more than 1400 branches, has implemented measures for Continuous Assurance, proving the viability and benefits of these measures. This institution has a CDA, a system which daily analyses more than five million accounts and generates about six thousand alerts a month. This system aims to increase productivity with efficiency and quality and its mission is to assess the risks and controls automatically and continuously in order to identify exceptions, anomalies, trends and indicators of risk; advise about controls, risk assessment; and contribute to the corporate governance. These features include all products, processes and services which enable data extraction and analysis. The taken approaches are of detection (routines to detect possible errors), of deterrence (routines to inhibit inappropriate behavior and events), financial (routines to reduce or avoid losses), and of compliance (routines to ensure compliance with applicable laws, policies and standards).

Recently, Marques *et al.* (2015) developed an innovative solution to implement Continuous Assurance services in information systems applicable to any business process, regardless of its type, dimension, business area or even its information system support technology, supported by an ontological model at an abstraction level that guarantees that contextual independence. The results analysis from an implementation of this solution allowed to ensure the feasibility and the effective use of the solution.

FUTURE RESEARCH DIRECTIONS

The limitations of Continuous Assurance that can be found in the chapter are likely to be the next future research topics in this area. A major limitation is in the CCM, because its implementation is complex due to the variety of control mechanisms it has to monitor in different business processes and contexts. A CCM which can be independent of the business processes and contexts was already implemented (Marques et al., 2015) although it is still very dependent on control mechanisms and on the initial system customization, which is a time-consuming and very hard task. Guerreiro, Marques and Gaaloul (2016) present a high-level conceptualization of an evolvable risk-based approach capable of self-learning the needs of monitoring, based on the continuous observation of business processes and of the results of continuous monitoring (approach with feedback control). This type of approaches has promising results and may be a future research direction.

Furthermore, a conceptualization of a model to assess the maturation of Continuous Assurance seems to be relevant to evaluate the services provided by the emergent solutions and, simultaneously, to follow the evolution of Continuous Assurance.

CONCLUSION

Although Continuous Assurance is not a concept firmly established yet, it is clear that it is maturing both in practice and in research because of its proven benefits in various organizational branches. In the public sector, the health service, social security institutions, tax administration, banking can be stated as examples. In the private sector, any organization can benefit from the implementation of Continuous Assurance, although those with greater resources are more able to bear it and keep it, for example, the areas of banking and telecommunications.

Furthermore, recent researches have proved the feasibility of implementation of information systems with full services of Continuous Assurance, covering all components and levels of objectives, to any business area and any type, dimension and nature of business process, providing very positive outcomes to the operational performance and accountability of organizations.

KEY TERMS AND DEFINITIONS

Continuous Assurance: Set of services which, making use of technology, uses the information immediately and produces audit results simultaneously or within a short period of time after the occurrence of relevant events.

Continuous Auditing: Activities undertaken to assess the business compliance to rules, policies or legislation, providing warranty and credibility to operations.

Continuous Monitoring: Process responsible for the management of internal control mechanisms in order to ensure their effectiveness, allowing to obtain timely information about transactions.

Explaining and Predicting Users' Continuance Usage Intention Toward E-Filing Utilizing Technology Continuance Theory

B

Santhanamery T.

Universiti Teknologi MARA, Malaysia

T. Ramayah

University Sains Malaysia, Malaysia

INTRODUCTION

Continuance usage intention is vital in today's environment because the longer a business firm can keep a customer; the greater the life-time revenue from that customer and at the same time the cost of serving the customer declines (Mittal & Lassar, 1998). Besides that the high level of user continuance usage intention is also a reflection that the program or the product is well designed and implemented (Lin, Chen & Fang, 2011) and it ensures the continued existence of many customer based electronic commerce firms (Bhattacharjee, 2001). Moreover, although initial acceptance is important in recognizing the success of an information system (Bhattacharjee, 2001) but continued usage is even more significant in ensuring the long-term viability of technology innovations (Premkumar & Bhattacharjee, 2008). Furthermore, Devaraj and Kohli (2003) argued that the long term usage of a technology will enhance the financial and quality performance of an organization. Thus, it is important for businesses to accentuate on continuance usage intention as the key for long term growth.

Guided by Vision 2020, Malaysia has embarked on an ambitious plan by launching the Multimedia Super Corridor (MSC) in August 1996. Seven specific flagship applications were identified as the pioneering MSC projects, which

includes e-government as one of the flagships (Muhammad Rais & Nazariah, 2003). The Vision of e-government is to transform administrative process and service delivery through the use of ICT and multimedia (Lean, Zailani, Ramayah and Fernando, 2009). The projects under the e-Government flagship have been started since ten years ago aimed at building a more effective and efficient way to communicate and transact with the citizens and industries. One of the projects under e-government flagship is Online Tax System or e-Filing (Hussein, Mohamed, Ahlan, Mahmud & Aditiawarman (2010).

BACKGROUND

The e-Filing system in Malaysia which was introduced in 2006 by IRBM is receiving much attention and there has been an upward trend in the adoption of the system among taxpayers with the latest income tax submission of 2,330,298 via e-filing in 2014 (Annual Report, 2014). Among the factors that could have contributed to this increase are convenience, faster refund and cheaper cost. However, according to Bhattacharjee (2001), while initial acceptance of information system (IS) is very important toward realizing IS success but its eventual success depend on its continued use rather than first-time use.

In this vein, investigating the continuance usage intention of e-filing system is deemed to be important because as more citizens use e-filing services, the more operation and management costs are reduced (Wangpipatwong, Chutimaskul & Papasratorn, 2008). In Malaysia, IRBM has saved millions of ringgit annually by reducing cost of printing, imaging, postal and storage through their e-filing system. In 2009, a total cost of RM9, 162,845.92 has been saved via the e-filing submission of tax (Hasmah, 2009). Apart from that, Bhatnagar (2009) reveals that governments are spending millions of dollars to build online service delivery portals in terms of hardware, software, training and maintenance and communication infrastructure. In developing the e-filing system in Malaysia, millions of ringgit has been invested (Aziz & Idris, 2012; Azmi & Kamarulzaman, 2010) especially to upgrade the agency's computer hardware and software (Bernama, 2005). Therefore, in ensuring that the heavy investments invested in developing the e-filing online portals will not be wasteful, identifying the factors that will motivate the continuance usage intention is crucial.

As such, this paper has focused in determining the effect of two main central construct in determining the individual adoption; satisfaction and attitude, towards continuance usage intention.

LITERATURE REVIEW

Technology Continuance Theory

Technology Continuance Theory (TCT) by Liao, Palvia and Chen (2009) is the newest theory introduced in the context of predicting the individuals continuance usage behavior; This new theory is actually a combination of three previous theoretical models which has been widely used in predicting the user behavior in IS acceptance and continuance, namely the Technology Acceptance Model (TAM), Expectation Confirmation Model (ECM) and Cognitive Model (COG).

The major contribution by TCT according to Liao et al. (2009) is it combined two main central constructs; satisfaction and attitude; into one continuance model. So, it is applicable for all levels of adoption such as initial, short term and long term users. TCT is believed to represent an improvement over TAM, ECM and COG models in terms of applicability and explanatory power. Based on the research done by Liao et al. (2009), they found that although satisfaction has a temporary effect on behavioral intention but it is still subjected for rejection or willingness to continuously use a system in short term. However, they also revealed that the success of information system in long term is determined by users' attitude.

Figure 1. Theoretical framework

Relationship Between Confirmation, Satisfaction and Perceived Usefulness

It has been found that a positive relationship exists between confirmation and satisfaction and perceived usefulness towards continuance usage intentions by many previous studies. Hwang, Yu, Tsai and Lin (2011) investigated the effect of confirmation on satisfaction and perceived usefulness on the continuance usage intention of e-portfolio learning system and found that confirmation has a positive effect on perceived usefulness and satisfaction. Alike, Lee and Kwon (2010) studied the effect of confirmation on satisfaction and perceived usefulness in determining continuance intention of web based services and found that confirmation positively influence users satisfaction and perceived usefulness. The study also shows that the effect of confirmation on satisfaction is much higher than perceived usefulness. Similarly, confirmation of expectation was found to be positively associated with perceived usefulness and user satisfaction in determining the mobile data services continuance intention among university students in South Korea (Kim, 2010). As such, it is hypothesized that:

H1: Confirmation has a direct positive relationship on satisfaction towards e-filing continuance usage intentions.

H2: Confirmation has a direct positive relationship on perceived usefulness towards e-filing continuance usage intentions.

Relationship Between Perceived Usefulness and Satisfaction

Previous researchers have confirmed a significant positive relationship between perceived usefulness and satisfaction towards continuance usage intention. Islam (2012) based on the study on the motivation to continue e-learning system use found that perceived usefulness has a significant positive impact on satisfaction towards continu-

ance intention. Hung, Chang and Hwang (2011) in exploring the continuance intention of the web based learning system found that the perception of perceived usefulness of the system has a positive influence on satisfaction towards continuance intention. Further, Shih, Shiau and Huang (2010) supported the previous study and disclosed that perceived usefulness has a significant relationship towards satisfaction in determining the bloggers continuance intention to engage in blogging activities. Correspondingly, Kang and Lee (2010) found perceived usefulness as the most important antecedent of customer satisfaction towards continuance intention of online services. As such, it is hypothesized that:

H3: Perceived usefulness has a direct positive relationship on satisfaction towards e-filing continuance usage intentions.

Relationship Between Perceived Usefulness and Attitude, Perceived Ease of Use and Attitude and Perceived Ease of Use and Perceived Usefulness

It is found that significant positive relationship exists between perceived ease of use and perceived usefulness and attitude which is proven by previous researches in post adoption environment. Lin (2011) based on their study reveals that perceived ease of use has a significant effect on perceived usefulness which in turn affects the attitude towards e-learning. The study also found that perceived ease of use has a greater effect on attitude toward e-learning for users with limited learning experience while perceived usefulness has a more effect on attitude for experienced users. This is supported by Suki and Ramayah (2010) whose study found that when a system is perceived as useful the user will form a positive attitude towards the system and its effectiveness. Similarly another study on e-learning investigated the consumer's continuance intention and found that perceived usefulness and perceived ease of

use significantly related to attitude of consumers in determining the continuance usage intention. Subsequently, the research also found a positive relationship between perceived ease of use and perceived usefulness of e-learning (Lee, 2010). Further, study by Kim, Kim and Shin (2009) indicates that perceived ease of use is a strong predictor of perceived usefulness in the use of airline B2C e-Commerce websites (AB2CEWS). It further found a positive relationship between perceived ease of use and attitude and perceived usefulness and attitude towards use and re-use of AB2CEWS with a more prominent effect of perceived ease of use towards attitude. As such, it is hypothesized that:

H4: There is a direct positive relationship between perceived usefulness and attitude.

H5: There is a direct positive relationship between perceived ease of use and attitude.

H6: There is a direct positive relationship between perceived ease of use and perceived usefulness.

Relationship Between Perceived Usefulness and Continuance Usage Intention

Perceived usefulness was correlated with all technology usage. Research by Brahmasrene and Lee (2012) on online learning found that perceived usefulness strongly influence the intention to continue using online learning. Hung et al. (2011) found that perceived usefulness has a positive relationship in determining the continuance intention towards web based learning system. Similarly, Al-maghrabi, Dennis and Halliday (2011) also revealed that perceived usefulness is the main determinant of continuance intention of e-shopping in Saudi Arabia. Correspondingly, Shiau, Huang and Shih (2011) examined the continuance intention of blog users and reported that perceived usefulness of the blogs positively influence the blogger's intention to continually use blogs. As such, it is hypothesized that:

H7: Perceived usefulness has a direct positive relationship towards e-filing continuance usage intention.

Relationship Between Satisfaction and Continuance Usage Intention

Strong relationship between customer satisfaction and continuance usage intention has been established previously by numerous researches. Choi, Park and Park (2011) found that satisfaction has a positive effect on the tourist continual usage intention of mobile tourism information services. Similarly, continuance intention was also found to be positively affected by satisfaction in determining micro blogging service continuance intention (Zhao & Lu, 2012). Ong and Day (2010) found that the outcome of user satisfaction with Social Media Service such as You tube and Facebook is the continued usage of these services. Satisfaction also was found to be the strongest predictor of users' continuance intention of Enterprise Resource Planning system compared to individual differences such as personal innovativeness, computer anxiety and computer self-efficacy (Chou & Chen, 2009). As such, it is hypothesized that:

H8: Satisfaction has a positive significant relationship towards e-filing continuance usage intention.

Relationship Between Satisfaction and Attitude

Oliver (1980) viewed satisfaction as the main influence for post purchase attitude. Huang and Hsu (2009) found that the more satisfied the respondents with their past experience, the more favorable attitude towards revisiting Hong Kong, means that satisfaction on past visit experience had a positive effect on tourist attitude to revisit. Likewise, Mosavi and Ghaedi (2012) found that customer satisfaction positively influenced positive attitude. Further, according to Sivadas and Prewitt (2000), the key to customer retention is

favourable attitude and the favourable attitude can be created by satisfying the customers. Similarly, study on examining the critical factors that influence the learner's satisfaction on e-learning reported that instructor's attitude towards e-learning significantly affect the e-learners satisfaction (Sun, Tsai, Finger, Chen & Yeh, 2008). As such, it is hypothesized that:

H9: Satisfaction has a direct positive relationship on attitude towards e-filing continuance usage intention.

Relationship Between Attitude and Continuance Usage Intention

Studies on continuance intention of a particular technology have proved the significant relationship between attitude and continuance intention. Hsiao and Chou (2012) investigated the effect of attitude on the continuance usage intention of online gaming and found that attitude significantly influences the continuance intention of online gaming. Lee (2010) and Ho (2010) further found that attitude is significant predictor of users' continuance intention toward e-learning. Indeed, attitude was found to be a stronger influence on continuance intention compared to other antecedents in shaping continued ICT usage intention (Hsieh, Rail & Keil, 2008). The study also suggested that individuals who have usage experience, attitude will have a stronger impact on continuance intention. As such, it is hypothesized that:

H10: Attitude has a direct positive relationship towards e-filing continuance usage intention.

METHOD

Sampling

The non-probability purposive sampling was employed in this study. Purposive sampling or particularly judgment sampling occurs when re-

searchers select respondents to conform to some criterion (Cooper & Schindler, 2008). In this study, the sample selected were taxpayers who had used the e-filing system before at least once as the measures required them to express their willingness to continually use the e-filing system.

Settings

A total of 900 questionnaires were distributed among the taxpayers in Selangor and Kuala Lumpur, Malaysia using self-administered questionnaire. A total of 401 questionnaires were returned and out of it, 355 were completed whereas the other 46 were incomplete. As such, the response rate was 44.5%. The questionnaire consists of 8 sections. The first section elicited the screening question, the second section collected the demographic data, the third section extracted information on confirmation, section four measured the perceived usefulness, section five measured the perceived ease of use, section six measured the satisfaction, section seven measure the attitude and last section measured continuance intention.

Measures

The measures were all adapted from the published literature. The measures for continuance intention were from Bhattechejee (2001). Perceived Usefulness and Perceived Ease of Use were from Davis (1989). Confirmation was adapted from Bhattacharjee (2001). Satisfaction was adapted from Spreng, Mackenzie and Olshavsky (1996) and Liao et al. (2009). Attitude was adapted from Taylor and Todd (1995) and Liao et al. (2009).

Sample Profile

The demographic of the respondents tabulated in Table 1 were derived from descriptive analysis. The majority of the age group (23.3%) was in the category of 30-34 years old. Male (63.8%) outnumbered the females (36.2%). In terms of ethnicity, the majority of the respondents were

Table 1. Demographic of the Respondents

Age	Frequency	Percent
20-24 years	3	0.80

Malays (55.2%), followed by Chinese (25.0%) and Indians (19.8%) which somewhat reflects the ethnic group distribution in Malaysia. About 60.3% of the total respondents are highly educated with Bachelor degree and followed by Masters degree. The majority of the respondents (31.9%)

are earning within RM3000-RM3999 per month with majority (81.0%) are married respondents. Lastly, about 84.5% and 57.8% of the respondents claimed to have experience in computer usage and internet usage approximately 10 years and above, respectively.

Figure 2. Research model

DATA ANALYSIS

Smart PLS version 3.0, a variance based Structural Equation Modelling (SEM) was used to analyze the hypotheses generated. The two step analytical procedure suggested by Anderson and Gerbing (1988) was adopted to analyze data whereby the measurement model was evaluated first and then followed by the structural model. Also following the suggestion of Chin (1998), the bootstrapping method (500 resample) was done to determine the significant level of loadings, weights and path coefficients. The research model of this study is as below.

Measurement Model

Convergent validity is the degree to which the items that are indicators of a specific construct should converge or share a high proportion of variance in common (Hair, Black, Babin & Anderson, 2010). According to Hair et al. (2010), factor loadings and Average Variance Extracted (AVE) of more than 0.5 and Composite Reliability (CR) of 0.7 or

above is deemed to be acceptable. As can be seen from Table 2, all loadings and AVE are above 0.5 and the composite reliability values are more than 0.7. Therefore, we can conclude that convergent validity has been established.

Next, we assessed the Discriminant Validity which is the extent to which a construct is truly distinct from other constructs (Hair et al., 2010). This can be established by the low correlations between all the measure of the interest and the measure of other constructs. To address discriminant validity, the square root of the AVE is compared against the correlations of the other constructs, when the AVE extracted is greater than its correlations with all the other constructs then discriminant validity has been established (Fornell & Larcker, 1981) (refer Table 3).

Structural Model

The structural model represents the relationship between constructs or latent variables that were hypothesized in the research model. The goodness of the theoretical model is established by

Table 2. Result of the measurement model

PU	0.747	0.597	0.741	0.701	0.915	
Satisfaction	0.543	0.620	0.507	0.576	0.518	0.923

Note: Diagonal represents the square root of Average Variance Extracted (AVE) while the other entries represent squared correlations

the variance explained (R^2) of the endogenous constructs and the significance of all path estimates (Chin, 2010). Together the R^2 and the path coefficients indicate how well the data support the hypothesized model (Chin, 1998). Figure 3 and Table 4, shows the results of the structural model from the PLS output. Confirmation was significantly related towards Satisfaction ($\beta = 0.483$, $p < 0.01$) and Perceived Usefulness ($\beta = 0.190$, $p < 0.01$) thus supporting H1 and H2 of this study. Perceived Usefulness was found in this study to be significantly related to Satisfaction (β

$= 0.230$, $p < 0.01$), Attitude ($\beta = 0.509$, $p < 0.01$) and Continuance Intention ($\beta = 0.266$, $p < 0.01$), thus supporting H3, H4 and H7. Perceived Ease of Use was found to be statistically significant to Attitude ($\beta = 0.232$, $p < 0.01$) and Perceived Usefulness ($\beta = 0.563$, $p < 0.01$) thus supporting H5 and H6. Satisfaction was found to be significantly related to Attitude ($\beta = 0.145$, $p < 0.01$) but insignificantly related to Continuance Intention ($\beta = 0.038$), thus rejects H8 and supports H9. Attitude was significantly related to Continuance Intention ($\beta = 0.609$, $p < 0.01$), thus supports H10.

**p < 0.01

CONF Confirmation, SAT Satisfaction, PU Perceived Usefulness, ATT Attitude, PEOU Perceived Ease of Use, CINT Continuance Intention.

The study also has assessed the effect sizes (f^2). The effect size (f^2) is calculated based on the changes of the R^2 to determine the substantive influence of the predictor variable on the dependent variable (Thies & Albers, 2010). To measure the magnitude of the effect size Cohen's (1988) guideline was utilized which is 0.02, 0.15

and 0.35 signify small, medium and large effects respectively. Looking at the f^2 values in Table 4, it can be observed that nine out of ten relationships shows substantive impact whereby there were 5 relationships with small effect size, 3 with medium effect size and 1 with large effect size.

Table 5. Blindfolding results

	Q ²
Attitude	0.519
Continuance Intention	0.641
Perceived Usefulness	0.424
Satisfaction	0.345

Apart from that, “blindfolding” procedure was also performed to measure the predictive relevance (Q²) of the model fit. The Q² “represents a measure of how well observed values are reconstructed by the model and its parameter estimates” (Chin, 1998). Models with Q² greater than zero imply that the model has predictive relevance. Table 5 shows the result of the blindfolding results. Omission distance of 7 was utilized as Chin (1998) indicates that values between 5 and 10 are feasible (refer to Table 5).

DISCUSSION

The purpose of this study is to predict and to explain the continuance usage intention of e-filing system among taxpayers in Malaysia using two important central constructs; satisfaction and attitude. The findings of the research reveal that confirmation and perceived usefulness has a significant relationship towards satisfaction. This is in line with previous findings by Hwang et al., (2011), Lee and Kwon (2010), Kim (2010), Islam (2012) and Jiang (2011). However confirmation was found to be the best predictor of satisfaction compared to perceived usefulness. This coincide with previous findings which reveals perceived usefulness as secondary determinant to satisfaction (Lee & Kwon, 2010 ; Limayem & Cheung, 2008).

On the effect of confirmation and perceived ease of use on perceived usefulness, both have a significant relationship towards perceived usefulness. This is consistent with previous researches such as Hwang et al., (2011), Lee and Kwon (2010), Kim (2010), Lee (2010), Roca and Gagne

(2008). Perceived ease of use was found to be the main predictor of perceived usefulness. As such it indicates that for a voluntary system like e-filing system, the perceived ease of use is the first impression, once the taxpayers perceived it is easy to use then it will be considered useful.

Perceived usefulness, perceived ease of use and satisfaction shows a significant relationship towards attitude. Perceived usefulness was found to be an important predictor of attitude followed by perceived ease of use and satisfaction as the weakest predictor. Thus this finding supports the TAM model which stated that users' positive perception of usefulness towards any technology will lead to a positive attitude towards using the particular technology (Davis, Bagozzi & Warshaw, 1989). This is supported by previous researches such as Lin (2011), Lee (2010), Liang and Yeh (2011), Mosavi and Ghaedi (2012) and Sivadas and Prewitt (2000).

This study hypothesized three important variables; perceived usefulness, satisfaction and attitude to have direct relationship towards e-filing continuance usage intention. The findings reveals that perceived usefulness and attitude have significant relationship towards continuance usage intention (Li & Shi; 2012), Islam; 2012, Hsiao & Chiou; 2012, Lin; 2011, Liang & Yeh; 2011), while satisfaction to have an insignificant relationship. This contradicts with many previous findings which revealed a significant relationship such as Lin (2012), Chang and Zhu (2012), Lee (2010). This could imply that as e-filing system is a technology delivered by the government, taxpayers may be more concerned on its usefulness of the system in submitting their tax returns

safely, accurately and timely, with satisfaction has limited impact on continuance usage intention.

The model adopted in this study shows that the perceived usefulness and attitude can explain about 72.2% of the variance in continuance usage intention. These results showed that the model has relatively good predictive power on continuance usage intention. Further, the blindfolding result in Table 5 shows that the Q^2 are all above 0 which indicates the model has predictive relevance (Fornell & Cha, 1994).

The implication of the findings can be divided into two; theoretical and practical. Theoretically, this study adds to the growing body of literature that focus on the post adoption environment which is continuance usage intention. It also contributes to the evidence in support for the determinants of continuance usage intention of taxpayers especially in Malaysian context. Practically, since attitude was found to be the major predictor with high effect size towards e-filing continuance usage intention, the Inland Revenue Board Malaysia (IRBM) needs to pay more attention to implement awareness campaigns from time to time to encourage more taxpayers to use the e-filing system and to change their perception about the system.

Limitation and Suggestion for Future Research

Despite the useful findings of this study, there are several limitations that need to be acknowledged. Firstly, due to time and resource constraint the sample size of the study is only limited to 355 respondents. Secondly, the findings cannot be generalized extensively in Malaysia as the scope of the study is only limited to the taxpayers in Selangor and Kuala Lumpur only. As such, caution need to be taken when generalizing to the whole country. Lastly, this study only focus on predicting the effect of satisfaction, perceived usefulness, perceived ease of use, confirmation and attitude on continuance usage intention and does not incorporate the actual usage behaviour in the proposed model.

Therefore, this research can be done further in future by (1) expanding the study to other states in Malaysia, (2) extend the model by incorporating the actual usage behaviour or any other relevant variables such as personality or trust, (3) replicate the study to any other e-government services.

CONCLUSION

In this study, it was found that attitude is an important determinant of continuance usage intention. This finding confirms with several attitude models such as Theory of Reasoned Action (TRA), Technology Acceptance Model (TAM) and Theory of Planned Behaviour (TPB) that attitude has an important impact on behavioural intention. This is supported by Lin, Chen and Fang (2011) whose study rationalizes that attitude is a better predictor of intention compared to satisfaction due to the fact that attitude comprises of three components: cognition, affect and conation whereas satisfaction is only an affective component of attitude. As such, a change in attitude will have a high impact on continuance usage intention (Bhattacharjee & Premkumar, 2004).

KEY TERMS AND DEFINITIONS

Attitude: The characteristics of a user.

Confirmation: The evaluation of the performance of the system against the expectation of the users.

Continuance Intention: One's intention to continually use a system or reuse a system.

E-Filing: Filing income tax returns via electronically.

Perceived Usefulness: Perception that a particular system is useful in completing a job.

Perceived Ease of Use: Perception that a particular system is easy to use.

Satisfaction: One's pleasure response when a system meets their desire and wants.

Taxpayers: Individuals who are liable to pay the tax based on their income for a particular year.

Forecasting the Demand of Agricultural Crops/Commodity Using Business Intelligence Framework

INTRODUCTION

Business Intelligence (BI) has been around for more than a decade and is being used in various application domains. BI is about creating value for organizations based on data or, more precisely, facts. While it seems like another buzzword to describe what successful entrepreneurs have been doing for years, if not centuries, that is, using business common sense? From a modern business-value perspective, corporations use BI (Sherman, 2014; Prasad & Acharya, 2011) to enhance decision-making capabilities for managerial processes (e.g., planning, budgeting, controlling, assessing, measuring, forecasting and monitoring) and to ensure critical information is exploited in a timely manner. And computer systems are the tools that help us do that better, faster, and with more reliability. BI is a broad category of application programs and technologies for gathering, storing, analyzing and providing access to data to help enterprise users make better business decisions. BI (Sherman, 2014; Prasad & Acharya, 2011) applications support the activities of decision support, query and reporting, online analytical processing, statistical analysis, forecasting, and data mining. BI includes a set of concepts and methods to improve business decision making by

using fact-based support systems. BI has become synonymous with historical query and reporting tools for many years, the definition of BI in recent years has evolved to include technology that addresses data integration, predictive analytics and information deployment (Shmueli, Patel, & Bruce, 2010; Sherman, 2014; Prasad & Acharya, 2011). Predictive analytics often help companies address their most difficult business issues and achieve a competitive advantage in their respective markets. Forecasting is a discipline of analytics that provides the foundation for planning processes across organizations. Good forecasting provides a more accurate view of the future, helping an organization save time and reduce costs, while better serving its customers and managing its resources. When used with data integration and information deployment capabilities, forecasting becomes even more powerful by pulling from multiple data sources and disseminating forecast results consistently. Information technology for agricultural (Shmueli et al., 2010) use can be broadly classified for:

1. Tools which might be used to improve productivity
2. Tools which empower farmers to take informed and quality decisions

At present the information available for farmers is through conventional sources, which are slow and unreliable. As a result of the information not reaching in time to the farmers, there is lot of wastage in terms of crops getting spoiled, some crop getting excess production and some crops not getting produced at all. These factors ultimately result in controlling the prices of the commodities dependent upon a particular crop. Thus the Farmers would be in a position to take the benefit of the technology used in the proposed approach. BI allows the decision maker to understand their business environment in order to make informed decision. Decision-making requires evaluating performance (what happened), testing hypotheses (why and how things happened) and predicting future events (what may happen). Stated simply management needs to know if their strategies are sound if they are being carried out. Most formally a business intelligence system allows users to answer above-mentioned decisions. Forecasting involves predicting and analysis of the given data, which can be achieved by BI.

- **Predictive Analytics:** Predictive analytics represent any solution that supports the identification of meaningful patterns and correlations among variables in complex, structured, unstructured, historical, and potential future data sets for the purposes of predicting events and assessing the attractiveness of various courses of action.
- **Planning Decisions:** This includes analytical reporting based on a data warehouse (DW) (Shmueli et al., 2010) or data mart and operational reporting based on an operational database management system. Reporting tools often include pixel-perfect positioning of data and graphics, a scripting language equal in power to a full program programming language, and the ability to handle complex headers, footers, nested subtotals, and multiple report bands on a single page.

BACKGROUND

Over the next thirty-five years, global population is expected to reach nine billion people. This will increase collective expectation of economic growth, nutritional demand and the resources used for food production. In order to meet expected worldwide nutritional demand and global food needs the agricultural industries and farmers should maintain good agricultural practices. Many previous studies have put together projections of global food demand. These studies tend to make large commodity groupings such as cereals, oil-seeds, meats, etc. (Kruse, 2010)

Business intelligence (Sherman, 2014; Prasad & Acharya, 2011; Legorreta & Valentine, 2014) means different things to different people. In its simplest form, business intelligence is getting the right information to the right people at the right time so they can make decisions that ultimately improve performance. A more technical view of business intelligence usually centers on the process of, or applications and technologies for, gathering, forecasting, and storing, analyzing and providing access to data to help make better business decisions. Regardless of how you define it, business intelligence is proliferating and reaching more and more constituents inside and outside of your organization. Information demand, data volumes and audience populations are growing and will continue to grow exponentially. The increase in available information also affects forecasting because there are more inputs to consider in both volume and type.

BI evolves different types of platforms and tools with respect to different categories. Precisely those are defined as (Sherman, 2014; Prasad & Acharya, 2011; Esri's, 2014):

1. Enterprise BI platform,
2. Visual data and discovery tool,
3. Pure OLAP (online analytical processing) tool,
4. Database or packaged BI, and
5. Dashboard tool.

BI functionality becomes commoditized; buyers need to look for differentiation elsewhere in these platforms. It's not just about tool functionality; tight integration with enterprise ERP, ETL, Forecasting, portal (Hamilton, 2012), and desktop office applications can often break the tie when selecting a strategic enterprise BI platform. Elaborating these platforms is vital task.

1. **Enterprise BI Platform:** BI platform has ability to satisfy business users, developers and enterprise needs. Its sets the right balances between ease of use and sophistication in our opinion making process.
2. **Visual Data and Discovery Tool:** Data visualization is a rich, highly interactive visual tool that allow user to manipulate and interact with information directly. Data discovery is the discovery relationship between elements regardless of where data is stored.
3. **Pure OLAP (Online Analytical Processing) Tool:** Otherwise known as "slicing and dicing" analysis, online analytical processing (OLAP) tools allow a user to almost instantaneously regroup, reaggregate, and resort facts typically additive numbers like transaction amounts and account balances by any dimension.
4. **Database or Packaged BI:** These are products that are supplied as an option when you buy the database or packaged application software. Some of the functionality may be built in to the database and/or the application and not be available separately.
5. **Dashboards Tool:** Dashboards are interactive visualizations that mash up different historical, current, and/or predictive information into one efficient graphical user interface (GUI). Typically, dashboards display key performance indicators (KPIs) using visual cues.

Although business intelligence was synonymous with query and reporting tools for many years, many organizations have discovered that the effective use of information requires more

than reports that show historical data. In addition to the information delivery component of business intelligence, data integration and analytics are garnering just as much attention in overall business intelligence strategies. A platform for enterprise business intelligence routinely consists of the following categories of technologies like data integration capabilities for data connectivity, data quality, ETL (extract, transform and load) data migration, data synchronization and data federation (Shmueli et al., 2010; Ranjan, 2005).

Correct forecasting involves the following two steps:

1. Predictive analytics that includes predictive and descriptive modeling, forecasting, optimization, simulation, experimental design and more. Forecasting uses many specialized types of models, such as exponential smoothing, ARIMA and unobserved components.
2. Information delivery capabilities to surface information from consistent, companywide data, and provide a single view of the data on which all planning decisions can be based.

Each of these components should be integrated not only into the business intelligence platform but also with the existing investments in hardware and software. A comprehensive business intelligence platform will be able to access all the required data no matter where it resides and no matter what operating system is being used. The BI framework will move the data if necessary, store it properly, analyze it thoroughly and disseminate it to users through familiar interfaces.

DEMAND OF FORECASTING FOR AGRICULTURAL CROPS/COMMODITY

In today's world with increasing population and year on year decrease in the agricultural land, there is a burning need for efficient utilization of the available land so as to become self-sufficient. Also in India, food inflation stands in double digits because of increasing demand and shortage

in supply. To control the food inflationist's very essential to meet the demands within the territory. If it's possible to forecast the demands of major agricultural crops for coming years with an acceptable range of accuracy, then proper planning could be made by the government bodies so as to meet the food demands. Even the food articles prices could be regulated without harming the economy. Demand for selected crops in each coming years can be achieved by predictive analytics. This may result in projecting approximate demand for each year for a particular crop/commodity.

Forecasting is the process of making projections of demand for products by examining past and present performance levels, combined with assessment of available products and markets. Forecasts of agricultural production and prices are intended to be useful for farmers, governments, and agribusiness industries. Because of the special position of food production in a nation's security, governments have become both principal suppliers and main users of agricultural forecasts. They need internal forecasts to execute policies that provide technical and market support for the agricultural sector. Government publications routinely provide

private decision makers with commodity price and output forecasts at regional and national levels.

Commodities like Oils, Pulses, Rice, Sugar and wheat have been chosen for the research. Demand for selected commodities may vary over the years, so projecting the demands of each crops/commodity over the year is challenging. Forecasting demands can be considered for other crops/commodity of agriculture. The objective of this research was to develop a detailed forecasting of demand for agricultural crops/commodity. Forecasting of demands is categorized based on year wise and commodity wise.

PROPOSED APPROACH

Implementation process involves integrating different system modules present in the architecture. Architecture describes functionalities of different modules and their activities with respect to system. It also defines how system works and what will be the flow of activity. In forecasting the demand of agriculture crops/commodity, we describe different set of modules and their activities in Figure 1.

Figure 1. System architecture

In Figure 1 an unstructured raw data acts as an input to the business intelligent process that evolves ETL transformation (Shmueli, et al., 2010). Clustering, Normalization and loading are sub activities for ETL transformation, which will formally structures the unstructured data, which we fed into our system. After transformation the structured data will be stored in ARFF (Bouckaert, et al., 2013) (Attribute relation file format) format, these files are then processed in weka tool. Prediction and analysis technique will be applied to structured data. The values derived from prediction are stored in CSV (Comma separated values) file format and they are now analyzed based on year wise crop and commodity wise crop. The raw data required for making the analysis in csv format was obtained in the form of the demand of five crops for last fifteen years. The structure of raw data is shown in Figure 2, Even though the data obtained was structured, it was so mixed up and jumbled that it was not fit for making effective analysis. Also data contained many redundant entries, which needed to be removed before storing them in the database. So it was a necessity to perform the ETL (Extract, Transform and Load) operations on this raw data to make it suitable for analysis.

Methodology

ETL (Extract, Transform and Load) (Pentaho Community, 2014) is the primary step for applying the business intelligence. It mainly included all those preprocessing activities, which are required for transforming the data into a proper format, which are required for analysis. Pentaho's data integration tool was used for performing the ETL. It included three main activities namely:

1. Clustering,
2. Normalization, and
3. Loading.

Clustering

Cluster analysis or clustering is the task of assigning a set of objects into groups (called clusters) so

Figure 2. Structure of the RAW data as input

	A	B	C
1	Crop Nam	Year	Demand
2	Wheat	1981	45.6
3	Edible Oil	1983	4.1
4	Pulses	1983	10.1
5	Sugar	1983	9.7
6	Wheat	1983	47.9
7	Rice	1983	68.1
8	Edible Oil	1984	4.2
9	Pulses	1984	10.1
10	Sugar	1984	9.8
11	Wheat	1984	48.1
12	Rice	1984	68.7
13	Edible Oil	1985	4.5
14	Pulses	1985	10.2
15	Sugar	1985	10.2
16	Wheat	1985	48.3
17	Rice	1985	69.5
18	Edible Oil	1986	4.6
19	Pulses	1986	10.3
20	Sugar	1986	9.9
21	Wheat	1986	48.7
22	Rice	1986	70.9
23	Edible Oil	1987	4.7
24	Pulses	1987	10.3
25	Sugar	1987	10.1

that the objects in the same cluster are more similar (in some sense or another) to each other than to those in other clusters. Clustering (Shmueli, et al. 2010) is a main task of explorative data mining, and a common technique for statistical data analysis used in many fields, including machine learning, pattern recognition, image analysis, information retrieval, and bioinformatics. As it can be seen from Figure 2, the raw data is completely mixed up. So it has to be grouped into different clusters with each group containing the data relevant to particular crop. Pentaho's data integration tool is used for clustering. Input data from the file is fed to a switch case, which filtered the data based on specified condition. We made the group based on the crop name. So clusters of crops are formed. The output streams of the switch case are fed as an input to different files, which now contain the information relevant to each individual crop. This process and structure of the data obtained after this stage is shown in Figure 3.

Figure 3. Clustering based on the crop

Normalization

Normalization (Elmasri & Navathe, 2011) is the process of organizing the fields and tables of a relational database to minimize redundancy and dependency. Normalization usually involves dividing large tables into smaller (and less redundant) tables and defining relationships between them. The objective is to isolate data so that additions, deletions, and modifications of a field can be made in just one table and then propagated through the rest of the database via the defined relationships. The data obtained after clustering stage is redundant. As it can be seen from Figure 4 the crop name is redundantly repeated. So to normalize it we removed the crop name field from the file and the data is stored in a new file whose name is same as that of the crop name. Thus the data obtained is normalized and kept in 3NF form, where non-primary attribute demand is fully functionally

dependent on primary key year. The structure of the normalized data is shown in Figure 5.

Functional Dependencies

A functional dependency (Elmasri & Navathe, 2011) is a constraint between two sets of attributes from the database. Functional dependencies are the formal tool for analysis of relational schema that enables us to detect the redundancies present in the clustered crop wise data Figure 5. It also used to define the normal forms for relational schemas.

Definition

A functional dependency (Elmasri & Navathe, 2011), denoted by $\text{Year}[A] \rightarrow \text{Demand}[B]$, between two sets of attributes A and B that are subsets of R specifies a constraint on the possible tuples that can form a relation state r (Relational state) of

Figure 4. Clustered crop wise data

	A	B	C
1	Crop Name	Year	Demand
2	Rice	1,983	68.10
3	Rice	1,984	68.70
4	Rice	1,985	69.50
5	Rice	1,986	70.90
6	Rice	1,987	72.00
7	Rice	1,988	73.10
8	Rice	1,989	73.40
9	Rice	1,990	72.60
10	Rice	1,991	71.00
11	Rice	1,992	69.50
12	Rice	1,993	68.60
13	Rice	1,994	67.30
14	Rice	1,995	67.70
15	Rice	1,996	67.40
16	Rice	1,997	67.50
17	Rice	1,998	67.00
18	Rice	1,999	67.20
19	Rice	2,000	66.80
20	Rice	2,001	67.60
21	Rice	2,002	68.90
22	Rice	2,003	70.10
23	Rice	2,004	71.50
24	Rice	2,005	72.30
25	Rice	2,006	72.90

R. The constraint is that, for any two tuples t_1 and t_2 in r that have $t_1[A] = t_2[A]$, they must also have $t_1[B] = t_2[B]$ where $R = \{A_1, A_2, \dots, A_n\}$. This means that the values of the B component of a tuple in r depend on, or are determined by, the values of the A component; alternatively, the values of the A component of a tuple uniquely (or functionally) determine the values of the B component. We also say that there is a functional dependency from A to B, or that B is functionally dependent on A. Thus, A functionally determines B in a relation schema R if, and only if, whenever two tuples of $r(R)$ agree on their A-value, they must necessarily agree on their B value.

3rd Normal Form

B

The normal form (Elmasri & Navathe, 2011) of a relation refers to the highest normal form condition that it meets, and hence indicates the degree to which it has been normalized. Third normal form (3NF) is based on the concept of transitive dependency. A functional dependency $A \rightarrow B$ in a relation schema R is a transitive dependency if there exists a set of attributes Z in R that is neither a candidate key nor a subset of any key of R and both $A \rightarrow Z$ and $Z \rightarrow B$ hold. The dependency Demand [B] $\rightarrow$ Year [A] is transitive through Crop Name in Normalized crop data Figure 4.

Figure 5. Normalized crop data

	A	B
1	Year	Demand
2	1,983.00	68.10
3	1,984.00	68.70
4	1,985.00	69.50
5	1,986.00	70.90
6	1,987.00	72.00
7	1,988.00	73.10
8	1,989.00	73.40
9	1,990.00	72.60
10	1,991.00	71.00
11	1,992.00	69.50
12	1,993.00	68.60
13	1,994.00	67.30
14	1,995.00	67.70
15	1,996.00	67.40
16	1,997.00	67.50
17	1,998.00	67.00
18	1,999.00	67.20
19	2,000.00	66.80
20	2,001.00	67.60
21	2,002.00	68.90
22	2,003.00	70.10
23	2,004.00	71.50
24	2,005.00	72.30
25	2,006.00	72.90

Loading

The load phase loads the data into the end target, usually the data warehouse (DW) (Shmueli et al., 2010). Depending on the requirements of the organization, this process varies widely. Some data warehouses may overwrite existing information with cumulative information; frequently updating extract data is done on daily, weekly or monthly basis. Other DW (or even other parts of the same DW) may add new data in a historicized form, for example, hourly. To understand this, consider a DW that is required to maintain sales records of the last year. Then, the DW will overwrite any data that is older than a year with newer data. However, the entry of data for any one-year window will be made in a historicized manner. The timing and scope to replace or append are strategic design choices dependent on the time available and the business needs. More complex systems can maintain a history and audit trail of all changes to the data loaded in the DW. In this stage normalized data is loaded into database or a data warehouse is created. Postgres was used which is an open source DBMS. Separate table is created for each crop and the normalized data obtained from the previous stage are loaded into respective tables.

Forecasting the Demand

Enhancing BI with forecasting (SAS: Analytics, 2015) uses time series analysis; it is the process of using statistical techniques to model and explain a time-dependent series of data points. Time series forecasting is the process of using a model to generate predictions (forecasts) for future events based on known past events. Time series data has a natural temporal ordering - this differs from typical data mining/machine learning applications where each data point is an independent example of the concept to be learned, and the ordering of data points within a data set does not matter. Examples of time series applications include: capacity planning, inventory replenish-

ment, sales forecasting and future staffing levels. Weka (3.7.8) (Bouckaert, et al., 2013) now has a dedicated time series analysis environment that allows forecasting models to be developed, evaluated and visualized.

This environment takes the form of a plugin (Pentaho Community, 2014) tab in Weka's graphical Explorer user interface and can be installed via the package manager. Weka's time series framework takes a machine learning/data mining approach to modeling time series by transforming the data into a form those standard propositional learning algorithms can process. It does this by removing the temporal ordering of individual input examples by encoding the time dependency via additional input fields. These fields are sometimes referred to as "lagged" variables. Various other fields are also computed automatically to allow the algorithms to model trends and seasonality. After the data has been transformed, any of Weka's regression algorithms can be applied to learn a model. An obvious choice is to apply multiple linear regressions, but any method capable of predicting a continuous target can be applied - including powerful non-linear methods such as support vector machines for regression and model trees (decision trees with linear regression functions at the leaves). This approach to time series analysis and forecasting is often more powerful and more flexible than classical statistical techniques such as ARMA and ARIMA (Bouckaert, et al., 2013). The above-mentioned "core" time series-modeling environment is available as open-source free software in the CE version of Weka. The same functionality has also been wrapped in a Spoon Perspective plugin that allows users of Pentaho Data Integration (PDI) (Pentaho, 2014) to work with time series analysis within the Spoon PDI GUI. There is also a plugin step for PDI that allows models that have been exported from the time series-modeling environment to be loaded and used to make future forecasts as part of an ETL transformation.

The perspective and step plugin for PDI are part of the enterprise edition. In the proposed work

the normalized crop files as input are loaded into the weka-scoring tool. Parameters are adjusted so as to make the prediction for eight years. This is as shown in Figure 5. The predicted values from the weka tool are stored in respective csv files, which are later loaded into the database tables.

The predicted values are generally stored in csv file but inputs to the weka tool is given in the format of An ARFF (Attribute-Relation File Format) file is an ASCII text file that describes a list of instances sharing a set of attributes. ARFF files have two distinct sections. The first section is the Header information, which is followed the Data information. The Header of the ARFF file contains the name of the relation, a list of the attributes (the columns in the data), and their types.

EXPERIMENTATION AND RESULTS

This section discusses experimentation carried out on raw data related to various crops. Results are derived for two criteria, one is with respect to crop wise and another one is on year wise demand. These forecasting strategies will; help to analyze demands for the particular years and crops. Crop demand is presented in the form pie chart to easily understand year wise demand for particular crop. The crop demands for the year 2013-2020 have been predicted. Some sample crops like rice; oil, pulse, sugar and wheat have been taken for which their demand is estimated. By analyzing the line graphs market commodity fluctuation can be easily understood.

Deriving a New Perception of the Available Information

The forecasted values provide the demand for a particular crop in coming years. In other words it's a crop wise view. The crop wise view shows the demand for different crops in each year from already available information. For this, the predicted values from all the crop files are combined and separate files are generated which contain the demand for different crops in each year (Director of Economics, 2015). This is done using Switch/Case tool as shown in Figure 7.

The predicted values from all the five crops are fed as inputs to the Switch/Case tool. Values of the input stream are filtered based on year field as parameter. These filtered output stream values are fed to respective files so that each file contains five rows, which are the predicted demands of five different crops/Commodity. Values from these files are very helpful in generating the reports for year wise projection in later stage. Two kinds of reports are provided with two different perspectives of the forecasted information. These are namely:

- Year wise demand.
- Commodity wise demand.

Year Wise Demand Forecasting

This type of a report presents the demand for different crops in each coming years i.e. from 2013-2020. This is presented in the form of a pie

Figure 6. Normalized data being fed into scoring tool

Figure 7. Combined Crop Wise View

chart in Figure 8. Thus eight charts are produced, one for each year. This format of view is very helpful for reading and analyzing the demands for crops in any particular year. It provides the required information in an easily readable and understandable format.

Crop Wise Demand Forecasting

The demand for particular crop in different years is presented in the form of a line graph. Thus five graphs are produced, one for each crop. These graphs are as shown in Figure 9. This format of view is very helpful for reading and analyzing the demands for a particular crop in coming years. It provides the required information in an easily readable and understandable format. One can also see the fluctuation in demand over the years

DISCUSSION

The rate at which the population is growing in all the region of the world, demand for agricultural crops/commodity may tremendously increase. Demands can be drives from population growth, income of the people, inflation, globalization; non farming activities etc... It may leads to less production of agricultural crops, which will never fulfill the exact requirements, or demands of government/people.

To overcome this problem we have chosen sample crops like Oils, Pulses, Rice, Sugar and wheat, and demand for those crops over the years from 2013-2020 (Director of Economics, 2015) is discussed in our research.

Forecasting The Demand of Agricultural Crops/Commodity Using Business Intelligence

Figure 8. Forecasting of the demand - year wise

Framework extend us to work on weka tool using different set of data about the crops. Business intelligence provides data organization in such a way that the knowledge filters can easily associate with this data and turn it into information for any of the domain. Persons involved in business intelligence processes may use application software and other technologies to gather, store, analyze, and provide access to data, and present that data in a simple, useful manner. The software aids in Business performance management, and aims to help people make better business decisions by

making accurate, current, and relevant information available to them when they need it. Some businesses use data warehouses because they are a logical collection of information gathered from various operational databases for the purpose of creating business intelligence. We come across different technology provided by BI which are Extract, Transform and Loading (ETL); this platform also ensures that there are some techniques do exit for forecasting demand of agricultural crops and commodity forthcoming years.

Figure 9. Forecasting of the demand – commodity wise

Agricultural forecasting uses a wide range of techniques in a wide variety of situations. The largest group is outlook forecasts, mainly of production, at different national and regional aggregations. They have a long history and a detailed and specialized development of leading indicator analysis unique in forecasting. Emphasis, indeed one might say overemphasis, on econometric modeling of ever increasing complexity has been a hallmark of agricultural forecasting. It stems, perhaps, from the desire and the training of agricultural economists to explain phenomena rather than predict them. Often, analysts make conditional predictions or projections based on assumptions that are oversimplifications of any policy that might arise. The ratio of policy analysis to long-term forecasting appears higher in agricultural applications than elsewhere. If this review appears to have concentrated on short-term forecasting, it is because few published long-term forecasts were located.

Results found here conform generally to the beliefs held by forecasters. The conclusions

are drawn from published studies and there are many unpublished forecasts. Although the types of forecasts required are similar to those found in business, agricultural forecasters have made little use of univariate time series methods. More common in the general forecasting literature is attempts to mechanically calculate correct (i.e. well calibrated) forecast probability distributions.

Table 1. Different types of current BI techniques used

Sl.No	Techniques	Description
1	Predictive Modeling	Predicts a value for different set of data records and attributes.
2	Classification	Determines to which class a different data records belongs.
3.	Characterization and describing data mining.	Data distribution, dispersion and exception.
4	Association and correlation analysis.	Identify the relation between different attributes.

The problem was recognized in agricultural forecasting in the late 1970s. Table 1. (Ranjan, 2005) describes brief description about the BI techniques used in our research.

FUTURE RESEARCH DIRECTIONS

A much-needed development is to combine forecasting with decision making (the so-called decision support system). Agricultural economists because of their historical emphasis on the analysis of resource allocation decisions, are perhaps more likely to emphasize this area than are other forecasters. BI framework can predict demands of agricultural crops/commodity. Deep learning is another technology, which could be used for more realistic analysis in the future. Appropriate prediction of food supply over the global regions and shortage of supplies can be estimated to fulfill required food supplies. For futuristic scope we can also use this framework to predict the demands over 50 years across the globe.

CONCLUSION

In this paper it is shown how BI and open source tools could be used to make the forecasting. Good results could be obtained by using data mining techniques along with business intelligence. Also very effective reports and dashboards could be generated, which provide multidimensional perspective of the available information. These are very helpful in making dynamic decisions with greater accuracy and effectiveness. Better forecasting of the demands is possible, if other parameters like demography; food price, global demand and changing nature of food consumption among people are also considered. One of the other important factors would be the changing environmental condition.

Food supply is important to national security; various governments have attempted to quantify agricultural production and to exert some control

over it. In the beginning, simply collecting and tabulating data on the current agricultural situation was a major challenge, and agricultural statisticians played a major role in the development of statistical methods (National agricultural statistics, 2015; Department of Agriculture, 2012; Department of Agriculture, World Agriculture Supply and Demand Estimate Report, 2014). In the coming days forecasting the agricultural demands would be a challenging task, and BI framework can help achieve proper forecasting food requirements.

KEY TERMS AND DEFINITIONS

Business Intelligence: Business intelligence is getting the right information to the right people at the right time so they can make decisions that ultimately improve performance.

Clustering: The term clustering refers to the task of assigning a set of objects into groups (called clusters) so that the objects in the same cluster are more similar (in some sense or another) to each other than to those in other clusters.

Data Warehouse (DW): A data warehouse is a repository of information collected from multiple sources, stored under a unified schema, and usually residing at a single site.

ETL (Extract, Transform and Load): It is the primary step for applying the business intelligence. It mainly included all those preprocessing activities, which are required for transforming the data into a proper format, which are required for analysis.

Functional Dependencies: A functional dependency is a constraint between two sets of at-

tributes from the database. Functional dependencies are the formal tool for analysis of relational schema that enables us to detect the redundancies present in the clustered data.

Loading: The loading refers to the phase of loading the data into the end target, usually the data warehouse (DW).

Normalization: Normalization is the process of organizing the fields and tables of a relational database to minimize redundancy and dependency.

Predictive Analytics: Predictive analytics represent any solution that supports the identification of meaningful patterns and correlations among variables in complex, structured, unstructured, historical, and potential future data sets for the purposes of predicting events and assessing the attractiveness of various courses of action.

B

Integrated Data Architecture for Business

Richard Kumaradja

Renaissance Consulting, Indonesia

INTRODUCTION

According to (Kosala & Kumaradja, 2014), to achieve a better analytics capability business organizations must utilize three Business Analytics components altogether so that a 360 degree analysis or a more comprehensive view of data can be implemented. The three Business Analytics components are: Big Data Analytics Tools and custom applications, Data Analytics Tools and custom applications, Unstructured Data Analytics Tools and custom applications form the Analytics Layer of the Big Data Analytics within the Business Intelligence and Business Analytics framework proposed by (Kosala & Kumaradja, 2014). For convenience, the structure of the Big Data Analytics framework is shown in Figure 1.

As stated by (Kosala & Kumaradja, 2014), the integration methodology of the three analytics components in Figure 1 and how they can be utilized together to get a 360 degree analysis view of data could represent a major research effort in the next few years. One of those research areas is about the data integration framework between unstructured Hadoop or NoSQL systems to create a structured OLAP data structure, and its real business case studies.

The author believes that the data integration framework must consider all layers of the Big Data Analytics framework shown in Figure 1, namely, Data Layer, Data Acquisition Layer, Data Storage Layer and Analytics Layer. Therefore, the proposed data integration framework must consider the entire Big Data Analytics ecosystem as one integrated data architecture.

Figure 1. Big data analytics within the business intelligence and business analytics framework

DOI: 10.4018/978-1-5225-2255-3.ch074

The purpose of this article is to clarify and show the concept of an integrated data architecture as a foundation of a modern data architecture which has the potential of addressing and solving critical issues related to big data analytics implementation in business organizations. Eventually, the goal of this article is to improve the likelihood of successful big data analytics implementation in businesses.

BACKGROUND

In their article (Kosala & Kumaradjaja, 2014) has pointed to data integration framework between unstructured Hadoop or NoSQL systems to create a structured OLAP data structure as one of the promising future research areas in big data analytics. The issue, however, is that there are still some confusions about data integration as mentioned by (Russom, 2008). In the next section, the concept of data integration architecture will be clarified as well as the detailed explanation of the proposed integrated data architecture for business organizations.

MAIN FOCUS OF THE ARTICLE

The main focus of this article is to address the issues of data integration from the architectural point of view. Addressing the issues of data integration from the architectural point of view will lead to a better understanding of the current situation and better able to construct proposed solutions to those issues since architectural approach can give us a holistic and comprehensive view of the problems.

In this section, the data integration issues related to Big Data Analytics adoption will be discussed, and an integrated data architecture for implementing Big Data Analytics will be proposed.

Issues, Controversies, Problems

There are some issues and misunderstandings when we talk about data integration. (Russom, 2008) has stated that to a lot of people the term data integration architecture sounds like an oxymoron because they do not think that data integration has its own architecture. For example, some data warehouse professionals still use the methods and practices of the 1990s when data integration was subsumed into the larger data warehouse architecture. He also observed that many data integration specialists still cling to poor practice that's inherently anti-architectural by building one independent interface at a time. These misunderstandings are further exacerbated by the belief that using a vendor product for data integration automatically assures architecture.

The problems with the above misconception are:

- We can not address how architecture affects data integration's scalability, staffing, cost, and ability to support real time, master data management, SOA.
- We can not address interoperability with related integration and quality tools.

In other words, with the absence of data integration architecture, we will not be able to construct an integrated data architecture which is strongly independent, future-facing, productive, scalable and interoperable (Russom, 2008).

Why have this misconception and confusion about integrated data architecture persisted? The complexity and perception about the role of enterprise data warehouse are the major reasons behind the misconception.

Today, in most business organizations, data flow from diverse source systems such as ERP, CRM and supply chain applications where most enterprise data originates as well as non-traditional

sources such as social media and other internet-based data sources. Since these data have different models not to mention the structured and unstructured ones, the data must be transformed in the middle of the process in a variety of ways. Diverse interfaces are also required to connect these pieces together (Russom, 2008). That said, the complexity level is quite high just to organize into a data integration solution such that most people would prefer not to invest their time in formulating a holistic solution. Most will resort to a vendor product with the expectation that the product will deliver the solution by itself. This has led to misconception about integrated data architecture.

Another issue is the understanding about the role of enterprise data warehouse. Traditionally, data processing for analytic purposes follows a fairly static workflow (Brite Group, 2013). Enterprise data is structured with stable data models via enterprise applications such as ERP, CRM, SCM and billing systems. Then the data is extracted, transformed and loaded (ETL) using data extraction tool from the enterprise applications and transactional databases to a staging area where data standardization normalization occurs. Using the data warehouse, business analysts use data analytics tools to perform advanced analytics. Historically, the data extraction tools have only supported structured data primarily associated with data from internal applications. However, today, the advent of the web, mobile apps and social media has caused a fundamental change to the nature of data. Unlike the traditional enterprise data that is centralized, highly structured and easily manageable, this so-called Big Data is highly distributed, loosely structured, and increasingly large in volume. This has caused a fundamental change in the role of enterprise data warehouse as well since it is not only sufficient to accommodate structured data anymore.

The context of data integration becomes more complex such that it demands a holistic view of the proposed solution. Therefore, by constructing

data integration architecture, the overall goal of Big Data Analytics can be achieved.

Solutions and Recommendations

In this section, the proposed data integration architecture which will lead to an integrated data architecture for business organizations will be presented and discussed. The goals of constructing such an architecture are:

- Obtain an independent architectural description of a business organization's enterprise data consists of both structured and unstructured data which are productive, scalable and interoperable.
- Obtain a development standard derived from the architectural patterns.
- Obtain reusability and consistency through the architectural descriptions.

Once a business organization's implement an integrated data architecture the resulting ROI is obtained through standardized data analytics components which lead to increase productivity at a cost less than using various proprietary components. It is expected that an integrated data architecture may have significant impact in the next few years as more and more companies adopt Big Data Analytics as part of their strategic technology initiatives.

The proposed architecture is based on the Big Data Analytics within the Business Intelligence and Business Analytics Framework explained in (Kosala & Kumaradaja, 2014), and some recent research works about big data architectures and analytics.

In formulating the proposed architecture, it starts with the observation that the processing environment for big data analytics becomes increasingly complex. This complexity has driven us to take a different approach in formulating a data architecture which can accommodate both structured and unstructured data seamlessly for

Figure 2. Different stages of analytics based on type of information

analytics purposes. Figure 2 shows different stages of analytics based on the type of information (Sallam & Cearley, 2012).

Figure 2 shows that there are three types of information: structured, hybrid and content used in different stages of analytics namely: descriptive, diagnostic, predictive and prescriptive (Sallam & Cearley, 2012). The descriptive stage tells us what happened, the diagnostic stage tells us why certain things happened and what the key relationships are, the predictive stage tells us what will happen and can show us what if scenarios along with the risks, and the prescriptive stage tells us what should happen and can show us the best option and how to optimize. It can be seen from Figure 2 that hybrid information is used in all stages of analytics. The existence of hybrid data becomes a necessity since it is needed to perform advanced analytics. Therefore, an integrated data architecture is defined as a data architecture that can accommodate and formulate architectural description of hybrid data.

Furthermore, the proposed integrated data architecture forms an advanced data ecosystem shown in Figure 3.

It can be seen from Figure 3 that Advanced Data is at the center of the ecosystem where it is supported by six (6) critical elements:

- Scale-Out Databases deal with the support of SQL and NoSQL data to support storage platform of Big Data.
- EDW (Enterprise Data Warehouse) which must be augmented by enabling it to process structured or multi-structured data and pre-processing of raw data.
- Real-Time Analytics which is a relatively new field but becomes more and more important in the near future.
- Data Integration and Quality which forms the foundation of a solid Big Data.
- Distributed Processing which uses Hadoop technology to process and combine Big Data sources.
- Hardware & Security

Therefore, the proposed integrated data architecture is shown in Figure 4.

It can be seen from Figure 4 that there are four main components of an integrated data architecture:

1. Apache Hadoop Framework as the Main Distributed Processing

Apache Hadoop Framework, is a framework that allows for the distributed processing of large data

Figure 3. Advanced data ecosystem

Figure 4. Integrated data architecture for big data analytics

sets across clusters of commodity computers using a simple programming model.

It is designed to scale up from single servers to thousands of machines, each providing computation and storage. Rather than rely on hardware to deliver high-availability, the framework itself is designed to detect and handle failures at the application layer, thus delivering a highly-available service on top of a cluster of computers, each of which may be prone to failures.

There are two core components in Hadoop:

- Hadoop Distributed File System (HDFS), the storage
- MapReduce, the processor

The core components in Hadoop are shown in Figure 5. We can see from Figure 5 that besides the two components HDFS and MapReduce there are other components that form the Hadoop ecosystem. They are Hive which acts as a data warehouse within Hadoop environment, Hbase which is a column-oriented big table, Pig which is a scripting language and Mahout which is a machine learning tool. All these components are still evolving primarily driven by commercial demand.

The advantages of using Hadoop are:

- **It's Scalable:** New nodes can be added as needed and added without needing to change data formats, how data is loaded, how jobs are written, or the applications on top.
- **It's Cost Effective:** Hadoop brings massively parallel computing to commodity servers. The result is a sizeable decrease in the cost per terabyte of storage, which in turn makes it affordable to model all your data.
- **It's Flexible:** Hadoop is schema-less, and can absorb any type of data, structured or not, from any number of sources. Data from multiple sources can be joined and aggregated in arbitrary ways enabling deeper analyses than any one system can provide.
- **It's Fault Tolerant:** When you lose a node, the system redirects work to another location of the data and continues processing without missing a beat.

2. Hadoop Add-On(s) as the Advanced Component for Easy Administration

To accelerate development and delivery of Hadoop-based solutions, Hadoop vendors have developed add-ons component to enhance the

Figure 5. Core components of hadoop

Figure 6. Example of hadoop add-on components

basic functionalities and provide administration & monitoring functions. Figure 6 shows an example of the Hadoop add-ons developed by one of the leading Hadoop vendors.

It can be seen from Figure 6 that there is a Data Operating System called YARN (Yet Another Resource Negotiator) that glues the Data Access and Data Management components. Additionally, there are other components Governance & Integration, Security and Operations have been added to harden the system. In the Governance & Integration component, Data Workflow Lifecycle & Governance subcomponents have been added, in the Security component, Authentication, Authorization, Accounting & Data Protection subcomponents have been added and in the Operations component, Provision, Manage & Monitor as well as Scheduling subcomponents have been added. The component for deployment choice has been added as well such as types of operating systems (Windows or Linux) and the types of deliveries (On-Premises or Cloud-Based).

3. Data Virtualization Abstraction Layer

Data Virtualization logically abstracting data from different data sources and data types into an integrated virtual data layer consisting of multiple virtual data views. Virtual data views in this layer can be shared and queried on demand, and can also

published as data services that serve up real-time data in various format.

There are already many research works and articles dedicated to data virtualization, among them are (van der Lans, 2014), (CITO, 2014), (Yuhanna, 2015), (Chandramouly, Patil, Ramamurthy, Krishnan, & Story, 2013), (Ferguson, 2014) and (Szabo, 2011). All of these articles have indicated the benefits of implementing data virtualization in business organizations. The benefits, among others, are:

- **Increased Agility:** The agility of the IT system is significantly improved because developers only have to focus on what data is needed and what data must be manipulated such that less code is needed. Making changes is also easier because the applications have been decoupled from the data sources.
- **Improved Time-to-Market:** Since data can be integrated faster, it simplifies the implementation of new systems and their integration with existing systems. Therefore, the resulting impact is a significant improvement of time-to-market so that organizations can react faster.
- **Improved Productivity and Maintenance:** As indicated and explained above, integrating data and systems with data virtualization is easier than with

Figure 7. Conceptual view of data virtualization

many other integration technologies due to the decoupling of applications and data sources.

- Improved Data Quality:** Using a data virtualization server, validation and correction of new data can be conducted before the corresponding data is inserted and updated in the source systems. Furthermore, when there is a false data retrieved from source systems, the data virtualization server can apply all types of data cleansing operations. These operations produce a higher level of data quality.

Figure 7 shows the conceptual view of data virtualization.

4. Apache Hadoop Cluster

Normally any set of loosely connected or tightly connected computers that work together as a single system is called a cluster. In simple words, a computer cluster used for Hadoop is called Hadoop Cluster.

Hadoop Cluster is a special type of computational cluster designed for storing and analyzing vast amount of unstructured data in a distributed computing environment. These clusters run on low cost commodity computers. The conceptual view of a Hadoop Cluster is shown in Figure 8.

There are already successful business applications of using Hadoop Cluster, among them are Yahoo who have more than 10,000 machines running Hadoop and nearly one (1) petabyte of user data. Others are:

Figure 8. Conceptual view of a hadoop cluster

- **Search:** Amazon.
- **Log Processing:** Facebook, Yahoo.
- **Data Warehouse:** Facebook.
- **Video and Image Analysis:** New York Times.

Besides implementation in well known e-commerce companies, Hadoop has also been successfully implemented in many financial services companies such as Bank of America, Morgan Stanley, OCBC Bank, ANZ, Deutsche Bank and RBS.

FUTURE RESEARCH DIRECTIONS

The future research directions of the proposed integrated data architecture will be in two (2) areas:

1. Data Warehouse Replacement or Augmentation?

The replacement of EDW into Hadoop became a trend topic in the IT world since Hadoop brings better performance at lower cost than EDW. Since

the biggest cost in Big Data is storage, Figure 9 shows the storage cost comparison by using Hadoop based on the survey shown in (Hortonworks, 2014).

It can be seen in Figure 9 that the storage cost per raw TB of data for Hadoop is the lowest among in-premise systems. Therefore, using Hadoop for large scale data warehouse applications can significantly lower the TCO of corporate ICT systems. This will motivate many companies to rethink their data architectures. However, there is a critical question that must be addressed. The question is whether it is possible to replace the traditional EDW with a Hadoop ecosystem?

Based on the survey conducted by Gartner shown in (Elliot, 2014), there were 11% of the organizations surveyed in 2012 who said they will replace their EDWs with Hadoop, however, in 2013 the figures dropped to 5.22%. The resulting conclusion drawn from the survey is that there is no relationship between the EDW and Hadoop at the moment – instead they are going to be complimentary. RDBMS or MPP will not be replaced, but instead big data analytics professionals will

Figure 9. Hadoop storage cost comparison

Storage Type	Fully-loaded Cost Per Raw TB of Data (Min-Max Cost)
Cloud	< \$2,000
HADOOP	< \$3,300
Network Attached Storage (NAS)	\$12,000 - \$18,000
Engineered System	\$11,000 - \$20,000
Massively Parallel Processing (MPP)	\$21,000 - \$80,000
Storage Area Network (SAN)	\$37,500 - \$180,000

use the right tool for the right job – and that will very much be driven by price.

In the near future, the research should not be focused on replacing traditional EDWs with Hadoop but how to use Hadoop to augment their functions in the big data analytics ecosystem.

2. Stream Processing and Stream Analytics

This is a relatively new but very important area of Hadoop research. Some Hadoop vendors now provides the stream processing capability by combining it with Apache Storm in the data access component of Hadoop architecture. Future research should focus on its enhancement for real time analytics applications.

CONCLUSION

In this article, the concept of integrated data architecture from the viewpoint of structured and unstructured data, its importance for big data analytics, the components of integrated data architecture have been clarified. Toward the end, an integrated data architecture for business organizations and the main components of the architecture have been proposed and explained. In the end, there are some discussions about the

research directions of the proposed integrated data architecture with the expectation that it will increase the likelihood of successful big data analytics implementation.

KEY TERMS AND DEFINITIONS

Big Data: The size, speed and sorts of data that exceed an organization's traditional database capacity to access, integrate, store, and analyze for accurate and timely decision making.

Big Data Analytics: The process, techniques, and tools used to gain insights from Big Data so that the decision making process could be optimized.

Business Analytics: The broad use of data and quantitative analysis to make business decisions in corporations.

Data Mining: The computational process and technique to find and discover patterns from large data sets.

Data Virtualization: Data management approach that allows an application to retrieve and manipulate data without requiring technical details about the data.

Hadoop: An open source technology developed under Apache Software Foundation that can be used to process Big Data in a distributed manner.

NoSQL: A collection of non-relational database technologies that are designed to store unstructured web data or documents.

Structured Data: Data that is defined and organized in a structure. For example: data in tables, data in relational databases.

Text Mining: The use of data mining techniques to discover and extract patterns from text.

Unstructured Data: Data that has no identifiable structure. For example, images, videos, email, text documents, and web documents.

Web Mining: The use of data mining techniques to discover and extract information from web documents and services.

IT Strategy Follows Digitalization

B**Thomas Ochs***Villeroy & Boch, Germany***Ute Anna Riemann***SAP SE, Germany*

INTRODUCTION

Digitalization is one of the most powerful and important phenomenon than any technology innovation before (Nordstöm, 2015). Digitalization has an enormous value and with it everything has the capability to change (Salo, 2006). With the ability of changing the way, products and services are consumed by the suppliers, consumers and partners completely different ways traditional industries being blurred (Rai, A., Pavlou, Im, & Du, 2012; Ray, Muhana, & Barney, 2005; Sambamurthy, Bharadwaj, & Grover, 2003).

In this sense the question of a new IT strategy emerges as companies need to understand where to invest in digital technology and what it deserves to get the highest value out of this investment. Much of that investment concentrated on applying new technologies to existing products, practices and processes. Going mobile, adding analytics, or extending the online experience are essential considering the transformation of the business with digital, in the face of changing consumer expectations, options and information.

Refining the business and digitalize them is more than just extend the IT strategy with digitalization by new functions and processes. Digital is more than a set of technologies. It is about the abilities those technologies create. Digital is the application of information and technology to raise human performance and in this sense the human factor is the essence of digital transformation as it creates the type of value that leads to revenue. In addition – of course - goals for creating efficient

cies that largely drive down the cost of creating short-term benefits but drain the economy and growth needs to be considered. Digital technology has a transformation potential starting in its silos such mobile, cloud, process, customer, supply chain, etc. (Rai, Pavlou, Im, & Du, 2012; Klein, & Rai, 2009; Saraf, Langdon, & Gosain, 2007; D’Adderio, 2001). Now it is the time to go down to the essence of the IT strategy asking the question how can a business win using information and technology raising human performance.

DIGITALIZATION

Background

Currently we see a lot of information addressing the topic of digitalization. Beyond the pure buzz-word a lot of previously effective and useful assumptions, structures and procedures have to be adapted to become successful in the new digitalized world. Our chapter focuses on the company’s IT and highlights in detail what the required changes in its various levels and dimensions for corporate IT are to meet the new digital requirements. The idea of our chapter is to make the relevant levels and dimensions transparent, outline how the various elements interfere with each other and how this transforms the corporate IT in regards to its positions and importance of the company, the structure and processes within an IT organization and the requirements towards agility and skills.

What Does Digitalization Mean?

As a trend, the substantial growth in the output in the recent years has changed. What is now of importance for many firms is the adoption of 'customer orientation through the reengineering of the value proposition of the desires and expectations declared by customers. This requires an increases for of collaboration, information sharing and flexibility (Jarach, 2002). In that sense the digitalization creates new patterns of action for the companies and especially for the IT. In simplified terms, the digitalization impacts the IT in various ways which should be reflected in an appropriate IT strategy, IT organization and IT processes. The impact the digitalization has towards the IT is huge as digital tools is to increase the coordination and adaptation possibilities since many organizations are reaching for the goal that is changing. The coordination with help of IT is possible if initial investments and adaptations to IT are made. The focus is on simple product, service and money exchange rather than knowledge or informational exchange. To move into this new digital era as a traditional organization it is necessary to accelerate the digitization of business processes that goes should go beyond simply automating an existing process. Processes must be re-invented, including cutting the number of steps required, reducing the number of documents, developing automated decision making, and dealing with regulatory and fraud issues. In parallel the operating models, organizational structures, and roles need to be redesigned to match the reinvented processes. Data models have to be adjusted and rebuilt to enable better decision making, performance tracking, and customer insights. Real-time reports and dashboards on digital-process performance permit managers to address problems before they become critical. All this is just not possible once the IT stays in their traditional role!

Why Does Digitalization Force a New IT Strategy?

One of the biggest challenges for mainly every company in today's times and thus as well for any internal IT is the digital transformation that will have a massive impact on all businesses and business areas. This impact has a high importance not only for companies emerged in the digital age but as well for companies of the old economy and does have relevance for the business models, new competitors and competitions as well as chances and risks that have to be considered due to the new networks and digital possibilities.

To succeed in this new digital era a clearly formulated digital corporate strategy is a fundamental pre-requisite - all business areas need to learn to think and act "truly digital". The setting and tracing of a digital agenda needs to have top priority in every area of a company. In addition any company need to find an answer to the question how the existing business model will be affected and possibly change or have to be adapted due to the digital transformation.

The digitalization itself demands for a superior and strategic IT view – just not the pettiness in which we often remain. IT conveys a certain importance in this sense as with the right use of the new IT capabilities new chances and strategic competitive advantages can be generated (Agarwal, & Lucas, 2005). This consequently means that the thesis of Nicolas G. Carr from 2003 "IT doesn't matter" (Carr, 2003) is disconfirmed.

The power of a digital IT strategy lies in its scope and objectives. Therefore the question to be answered is how an Information Technology (IT) strategy should be developed.

While the IT strategy basically regulate the longer term deployment of information and communication systems of a company, it is difficult to define general rules for formulating them. In the

light of digitalization we believe that IT becomes a dominant role in the corporate strategy, i.e. where IT is used in internal and external operations to create a competitive advantage (Kohli, & Grover, 2008). Therefore the IT strategy is the pivotal point the digitalization. In this chapter we will first outline what – according to our understanding – defines a new digital IT strategy, the organizational governance and steering model required and the conditions under which such an IT strategy shall be developed. Following we will highlight the core elements of the strategy framework and the potential for transformational innovation.

Even though the fundamental understanding remains unchanged, that the business strategy and the priority initiatives need to be aligned to the business value and that the digitalization can only be successfully succeeded within a cooperative collaboration between business and IT (Bharadwaj, El Sawy, Pavlou, & Venkatraman, 2013). IT does need a new definition of its own role that goes beyond the IT operations and IT maintenance (Brynjolfsson, & Hitt, 2000; Devaraj, & Kohli, 2002; Santhanam, & Hartono, 2003). The questions to be answered need to address the scope, the scale and the core elements of the IT strategy with the following key questions that drive the definition of the IT strategy:

- What is our digital vision? And how does this vision impact our stakeholders?
- Where does the digital strategy fit in our company structure?
- What are our digital priorities?
- What is your business process maturity and standardization level?
- What sources of data will significantly change our business?
- How do you envision machine and people collaboration?
- What is your vision for real-time collaboration with suppliers and business partners?
- What is your strategy for the workforce?

- How are you digitizing your product and services?
- Do your employees have the right tools and information to drive effectiveness and reduce hierarchies?

The following chapter will highlight core elements of such a newly defined role and a target picture for a corporate IT.

Scale of the Digitalized IT Strategy

Today's internal information management is mainly concerned with the provisioning of a corporate IT infrastructure, the process support and the data management (Barua, & Mukhopadhyay, 2000). With the harmonization if the application landscape throughout the entire company as the key target as of now has already been achieved (Rai, Patnayakuni, & Patnayakuni, 2006): a globally used software landscape as a robust and trustworthy platform for the main business activities supporting the business processes effectively and efficiently has been put in place (Gartner, 2016). However, this target is no longer in the core focus – even more, there are new challenges arising at the horizon in the area of business process support: in addition to the process support the IT department need to step in into the role as a “business enabler” in order to let the company participate from the chances of the digitalization. No matter if these changes are disruptive or evolutionary for a company, IT has to take over a core role whereas the IT strategy is based on the digitalization (Melville, Kraemer, & Gurbaxani, 2006; Wade, & Hulland, 2004).

According to our understanding the emergence of the new digitalized IT strategy can be summarized as highlighted in the Figure 1:

We believe that the path forward for a true digitalization needs to be reflected in the way IT is perceived as a strategic element within the company and how agile IT is able to adapt to the new IT trends:

Figure 1. Emergence of the new digitalized IT strategy

- Cooperative Collaboration of the IT with Board, Top Management and Business:** It is essential to define the way the IT is organized and how the IT is linked to the company's management board as the key decision-making unit of a company. We believe, that the CIO and thus the Corporate IT need to be member of the board to build-in the increasing importance of the IT (Gartner, 2016). The link to the Corporate IT itself to the various business units need to be anchored with the establishment of dedicated key account roles making sure that the entire business spectrum as addressable and that the role of an internal consultancy and trusted advisor can be established (Baskerville, & Land, 2004).
- Continuous Consideration of IT Technology Trends:** Especially in the past 2-3 years newly developed IT technologies had a tremendous impact on the companies and their value proposition (Luftman, & McLean, 2004). This can be determined on the stellar ascent of the topic „Industry 4.0“ that is overall being celebrated as the 4th industrial revolution (Hames, 1994).

Based on the close alliance of computer technology with electronics and mechanics (Embedded Systems) and the “any-time-any-place” communication ability via internet (Internet of Things) new opportunities in production, logistics, sales and marketing leading to new types (smart) product and (smart) services emerge.

A further technology dynamics will be achieved due to the enhanced ability of mass data processing of various formats, data sources and structuring levels in real time (= big data) (Pavlou, & El Sawy, 2010). Linked with complex statistical concepts and methodologies (= Predictive Analytics) new possibilities of the gaining in knowledge and insight emerge that go far beyond the usual type of reporting functionalities As already described by Davenport the ability to analyze data becomes a critical capability for contemporary organizations (Davenport, 2006). Companies such as Google clearly stated: “the one that owns the data owns the key for success”.

Additionally the accessibility and velocity of IT usage has changed dramatically. Cloud-based solutions offer new possibilities in regards to a faster deployment, flexible usage, scalability, global accessibility and actuality (see NIST).

As previously said, the new IT role needs to be geared towards the digitalization and can be characterized with the following three core statements (Bharadwaj, El Sawy, Pavlou, & Venkatraman, 2013):

- **IT Shall Be the Pioneer of a New Digital Culture:** Within the digital world taking over risks becomes a cultural norm. Therefore the new digital culture has to embrace failure as a prerequisite for success. Whether culture drives technology adoption or whether technology changes the culture is still an open question. Beth Israel Deaconess' Halamka stands on the culture side of the question. "I have never seen a technology drive change on its own," he says. "Culture leads the adoption of technology. Our ability to innovate depends on the impatience of our culture." (Kane, 2015)
 - IT projects need to strive for the new digital culture.
 - Moreover, all acting and behaving need to be targeted to anchor this digital culture within the company.
 - IT needs to consequently ask the question how processes can be newly defined with the advantage of digital appliances.
 - All operations and maintenance activities need to be realized as efficient and effective as possible as this "operational obligation" shall not consume more time than necessary to leave space for the digital challenges.
- **IT Shall Promote Technological Innovation:**
 - The relevant IT technologies need to be identified and adapted at an early stage. In this sense the clumsiness of the IT application landscape needs to be overcome while a stable and global operations must be secured.
- The era of IT monoliths are over and will be replaced by an orientation on available market solutions integrated according to the Lego principle. This landscape will as well lead to solutions that are more agile and enable a faster provisioning of solutions to the business according to the 80:20 rule.
- The focus on standardization, speed, and user experience is key (Gartner, 2016). This leads as well to the usage of cloud solutions. The consistent application of a hybrid approach with the use of public cloud applications if a further market differentiation with an on premise solution is unrealistic.
- Service & Support needs to be productized based on globally standardized processes to gain freedom for the leadership role that allows an autonomous acting in pre-defined target corridor.
- **IT Shall Take Over Leadership:** IT needs to have a comprehensive knowledge in Best Practices in various disciplines to be applied that are core to the company (e.g. logistics, production,...). While having established this knowledge bases IT has potential of becoming a trusted advisor rather than being an assistant for the business.

Scope of the Digitalized IT Strategy

The scope of the digitalized IT strategy, expressed in vision and mission, is the essence of any strategy. Vision and mission contribute the key points to make the core elements transparent for the organization. The embodiment of the mission delivers the frame of the new IT strategy. The internal IT management is the core and corporate-wide solution provider for all information and telecommunication technology having the full sourcing-, organization- and architectural responsibility (Amit, & Schoemaker, 1993; Conner, & Prahalad,

Table 1. New orientation if the IT based on key characteristics

Characteristics	Description
Alignment with the business	The close alignment with the business is a key success factor and essential for the success within a digital environment.
Costs & Efficiencies	Turn away from a pure cost efficiency towards a cost optimization that balances the costs and benefits.
Degree of standardization	Move from a software monolith towards a multi-supplier strategy. Process harmonization and process integration remains a core target.
Localization	The internal information management was, is and will be centrally organized and allows localizations only where needed.
Maturity	The change from a stable software with a high level of maturity towards innovative and modern software solutions require to take the risk dealing of a less mature software within the company.
Size of the IT	The IT will grow compared to other business units. However, the core elements of the IT organization remains stable such as leadership, demand generation, application design, support and maintenance.
Competency and Organizational Culture	The required skill and competencies of the OT staff will change dramatically. The classical IT competencies (e.g. IT administration) will decline in its importance where the new challenges such as flexibility diversity, digital native and innovative behavior grow in its importance.

1996; Wernerfelt, 1995). Therefore, the IT is the natural innovation partner when it comes to digitalization and has a key responsibility within the proactive identification and analysis of IT technology trends to further increase the value of the company (process optimization, revenue potentials, etc.) (Berger, & Ofek, 1995; Lang, & Stulz, 1994). An additional core element is the holistic realization of projects including the support of the required transformation. It will no longer remain in their core competency of purely deliver the IT components but support a sustainable value proposition with a continuous support of the business leading to a continuous change process and management. Furthermore IT will still take

care of the design and standardization of business processes to achieve a degree of business process excellence, the provisioning of IT solutions and applications that meet the requirements of the requesters in regards to usability (user experience) and performance (Gartner, 2016). To secure this timely and efficient provisioning of new applications and features, agile methodologies and the usage of the so 80:20 rule will be applied to shorten the time to market. The guarantee of an appropriate data security and data protection that meets the legal requirements will still remain a core target. The following Table 1 outlines the strategic reorientation of the IT with its core characteristics.

Scope and Principles of the Digitalized IT Strategy

IT Organization

To meet the new requirements the digitalization asks for, the IT organization needs to be adapted in regards to organizational structure, number of employees, roles, profiles and competencies. Core element of the new organizational structure should be competence centers to bundle core competencies and the End-to-End process knowledge (Collins, & Porras, 1996). The further development of the employees must be oriented towards the new tasks of the IT – formulated in the new roles of Table 1 which is mainly transformation management, integration abilities, creativity and flexibility. The ability to adapt quickly to change also stands out as an important capability. According to Perry Hewitt agility is more important than technology skills. Emory professor Konsynski concurs: “The 21st century is about agility, adjustment, adaptation and creating new opportunities (Buschek, 2015). Table 2 gives a brief overview of the new organizational elements within a modern IT organization.

For being able to live up to all new activities and tasks we assume to increase the headcount of the internal IT organization by 10% within the

Table 2. New organizational elements of a modern IT organization

Role	Description
Usability Lab	Implement a cross-functional team across all applications to secure an enhanced and state-of-the-art usability for all core applications. To gain further impact a specific usability lab concentrates all activities on this topic.
Digitalization and innovation hub	Establish a dedicated organizational unit at a trend-setting location with access to „Digital Natives“, where Trend Scouts and Business Transformation Manager work together as a co-innovation team.
Shared Service Center	Set-up a team with specialized duties in regards to software development and Application LiveCycle Management (ALM).
IT Management	Global structuring of the entire IT organization with regional managers to directly address regional specifics without losing the global directive of the core IT.

next 3-4 years. In addition the core competency of the IT employees will shift towards the new digital requirements e.g. Solution Designer, Usability experts, Project Manager for digitalization projects, technology trend scouts, data scientist and data mining specialists for big data.

IT Steering- and Governance Model

Companies are and will be increasingly confronted with considerations that are less related with business and more about work, people and society as such. For anchoring the required new structures, roles and processes it is necessary to establish a new and corresponding steering and governance model that comprises the new planning process, portfolio management, internal process steering and IT controlling. The crux is to know what to digitize and automate and how to achieve this. Therefore, this new steering and governance model needs to be structured in a way to allow a better value creation through innovation, flawless execution and intense collaboration. It needs to be driven by the target to digitalize as much as possible and as consequent as possible to not ample opportunities to optimize business processes, better focus customer experience and employees

satisfaction. Overall, a stronger collaboration and synchronization between all business partners is required in this new digital era. The following table describes the elements of a new level of governance dedicated to ensuring the success of the digital strategy. It outlines the core elements and responsibilities of the modernized steering and governance model as stated in Table 3.

IT Infrastructure

The development of an IT strategy, must take into account what is happening in the external environment in order not to miss opportunities and possible threats (Bharadwaj, El Sawy, Pavlou, & Venkatraman, 2013). This includes as well new technologies. A retrospective view over the last decades shows that the IT strategies chosen by companies seem to have followed three general strategic tendencies: In the 1980s and 1990s, the main priority for companies was to integrate business processes. Achieving this integration by implementing integrated systems was hugely beneficial. As globalization increased, the attention shifted to efficiency improvements. The decentralized structures were suddenly perceived as “road blockers” and as obstructing control and reporting processes and as limiting transparency. For IT, this meant developing consolidation strategies to achieve global harmonization of processes, data, and systems (Davidow, & Malone, 1992). From a technological perspective, the web offered an excellent base for the global harmonization projects, but they turned out to be complex, time-consuming and they cost a lot of money. In around 2005, a new paradigm emerged which promised to be the savior in the dilemma of global standardization versus dynamic adaptation: “service-oriented architecture” (SOA). Nowadays, while service-oriented architecture stays a relevant architecture component, a discernible trend away from centralized standards, and back to peripheral control, is emerging. As a consequence of the changed requirements in regards to the IT business-support the business usage

Table 3. New steering and governance model

Element	Definition
Portfolio Management	The fit of the IT architecture as well as the mid- to long-term project roadmap is if strategic priority. The collaboration of IT with the Top Management across all business units is essential to guarantee the synchronicity with the business targets. Additionally the implementation and tracking of key KPIs to measure value creation and implement corrective actions is essential.
Planning Process	The planning process needs to be set up efficiently and lean meaning that the entire planning shall be on a contingency level rather than on a detailed level. This contingency planning will allow a controlling on a flexibility level that allows an adjustment where needed. Furthermore it supports to shift budgets from 'keeping the lights on' to innovation and value creation
Steering and Reporting	To give the increasing importance of the IT topics the appropriate standing within the company it is necessary to establish a new and dedicated decision-making body to address the new topics of digitalization. This newly established committee needs to balance the digitalization topics in the light of executive finance and IT.
Digitalization as core element of the IT project portfolio	The definition of a company-wide valuation of projects in regards to their digitalization relevance to provide a framework to consequently adjust all activities to this core targets.
Master Data Management a score competency	Data will be more tightly infused into processes. Therefore it is essential to position master data management as a core IT competency. Even though master data management is not a digitalization asset at first sight the process responsibility on an end-to-end perspective deserves a high master data quality.
Profit Center structure for IT controlling	Due to the increase responsibility we believe it is essential to structure the entire cost control as a profit center structure to allow an increase transparency on costs but as well to provide a unified and appropriate accounting for IT services.

and the capabilities driven by newly developed IT tools and accelerators the IT infrastructure needs to be enhance with cloud-based and mobile components. Cloud computing became the new way of delivering and charging for services and functionality. For internal IT this means to give away some control over service areas, as it will no longer be provided through the IT department. For the business side cloud computing offers a higher flexibility, as services can be ordered and delivered on shorter notice and paid as variable costs. Therefore, we believe the following strategic guidance, outlined in Table 4, shall be seen as a support to address these required adaptations.

IT Service and Product Portfolio

An adequate IT service level and product portfolio is essential to cope with the expected business requirements. This operational excellence means

bringing business processes to a standardized and productized level, avoiding interfaces or integration gaps wherever possible, and having full transparency regarding key service performance. It deserves as well that IT itself provides an excellence in regards real-time insight into important company data, stability, digital security, and agility.

IT Sourcing Strategy

The sourcing strategy adds a significant part towards the overall productivity of the IT and thus of the company. In terms of the effect of digitalization, the feature to highlight is that IT has continued to improve efficiency for a long period of time and digitalization is now making inroads towards improving efficiency in services as well. Looking ahead, we expect that much of the future productivity resides in improved services.

Table 4. Adapted IT infrastructure

Infrastructure Element	Adaptation
Hybrid IT infrastructure with an increased connectivity	The hybrid IT infrastructure shall consist of “On-premise” and cloud components. “On-premise” refers mainly to the classical operations with buying or renting the IT component together with the IT operations in own responsibility. By contrast, cloud means a purely user-oriented consumption of IT functionalities and a corresponding pricing. Depending on the level of consumed services we need to differentiate between Infrastructure-as-a-Service (IaaS), Platform-as-a-Service (PaaS) and Software-as-a-Service (SaaS). Overall, we can state that cloud will offer a higher degree of cost flexibility, the safe-guarding of a consistent and timely modernization of the used IT components and a better realization of the “Economics of Scale” due to a bundling of service providers within the community of all users of a service. In case a service shall be used exclusively for a certain community there is the ability of a cloud-service usage in a private cloud. In this sense, public cloud components shall be advised to be considered in case the IT support is not seen as a competitive differentiator and where the data security is sufficiently provided within the cloud environment. This is where it is essential to balance the On-premise combination with the Public Cloud components in a hybrid IT environment. In a world of hybrid deployment models, high connectivity (Business Network and omni-channel), Big Data and Internet of Things, implementation and operations have to be in-sync more than ever to allow velocity, innovation, stronger technology adoption and much lower operational risk.
Build-in international IT security levels	In general the IT infrastructure needs to meet EU and international security levels to address the increased requirements towards data protection and data security. This can be achieved by appropriate firewalls, authentication methodologies and certifications (e.g. ISO 27001, IDW 951, etc.) This is where it is necessary to keep a special attention on service suppliers that are outside the EU data protection guideline
Mobile IT Technology	The mobile usage of IT technology is mandatory and becomes the new standard. With the increasing prevalence of web technologies (Curbera, et al., 2002), employees now have access to company data via the Internet (“anywhere”), which facilitates e.g. work from home or at a customer’s site (Aungst, & Wilson, 2005; Sinisalo, Salo, Karjaluo, & Leppäniemi, 2006). Smart mobile devices offer further opportunities to optimize many business processes (“any service, anywhere, anyhow”). Mobile connectivity is undoubtedly becoming an important building block in any digital eEnterprise Therefore all applications need to be available on any end-user devices – especially on the mobile devices (e.g. tablets or smartphones) – within an easy-to-go way. This needs correspond to the availability of the wireless infrastructure and the contracts with these external providers (e.g. global flat rate for calls and data).
Globally standardized catalog for end-user devices	With the provisioning of a globally standardized set of IT end-user devices that is mandatory for all users a comprehensive but manageable portfolio will be provided to support the mobile strategy at the most cost-effective way.
Centralized user authentication	A centralized authentication platform for every IT infrastructure and application used within a company with a single-sign-on is core to support the convenience of the users together with the security requirements.

Following, we will following present an overall view of where the IT sourcing strategy is headed.

- Increase the percentage of external sourcing to accomplish a better coverage of specific IT demands.
- Professionalize the multi-vendor strategy in regards to globally binding service levels, escalation processes, reporting structures and warranty rules.
- Global validity of software contracts to realize cost effects with the bundling of demands as well as to better manage compliance regulations based on software license contracts.
- Extended use of external service providers to flexible and better capture capacity peaks and thus to avoid delivery and project delays.
- Outsourcing keeps a core element of the IT operations to benefit from the lower cost level, cost flexibility and to meet the issues of resource shortages of IT specialists (Dos Santos, 2003).

Table 5. New IT service and product portfolio

Topic	Definition
Global Service and Support	Establish a professional and global acting application lifecycle management (ALM) with dedicated service levels per application and coverage of the “follow the sun” principle
Trusted advisor	Establish a professional and comprehensive consulting service based on an in-depth knowledge of IT methodologies and business know how
Streamlined IT product catalogue	Develop an IT product catalogue focused on end-user oriented topics, necessities and applications
End-user devices	Provide a broad catalogue of end-user devices oriented towards the technological developments, application and business needs and tailored to the most appropriate usage
Flexible IT usage	Turn away from the standard cost charging of IT towards a used-on demand concept of IT services. The shall be a flexibility to book and decline the usage of IT services and a transparency on the charges for the consumed services
Global service levels	Deliver the IT service deliveries towards a unified, company-wide and standardized service level agreements (SLAs). A monitoring of the various categories and deliveries supported with customer satisfaction surveys shall be performed on a regular basis
Process Re-Engineering	The analysis and fact-based re-design of business processes will emerge towards a core IT competency. Even though this is not a brand-new topics we still waste huge amounts of time and money because we still rely on expensive manual and slow paper-based processes. I these areas digitization is the transformation of information into digital formats and ultimately the digitization of business processes.

IT Applications

The business requirements towards the IT applications will increase due to the digitalization as they emerge from a process support to a business enabler. Having this role emergence in mind we can draw 5 key principles for the IT applications:

- **Principle 1:** Overall target is a well-balanced hybrid IT application landscape.
- **Principle 2:** User friendliness becomes a core target of the entire application development and application provisioning with an appropriate quality level delivered out of the new usability lab.
- **Principle 3:** Increase use of Apps to support business processing is essential to ease the handling of functionalities and create user-centric rather than system-centric applications, processes and workflows – in parallel the expert mode shall be maintained as well. This user centricity includes a strong focus on user value and the best possible interaction with the business, and

intuitive “from-where-you-are” access to important information or processes.

- **Principle 4:** Extend the use of public cloud applications to allow a networked collaboration within the company to enable a paperless process and a truly digital workplace.
- **Principle 5:** No release of new applications without user acceptance tests as a mandatory asset of every IT implementation to systematically increase the applications quality.

CONCLUSION

Over the last decades, the central points of view of IT strategy has been that it is a supportive strategy that must necessarily been derived from the company’s strategy and that focuses on the support of processes with a high degree of process standardization leading to cost effectiveness. Now business becomes digital with increased IT elements among products, services and processes. This is as well true for companies in the old

economy where the digital technology transforms the entire business of a company. Consequently we believe that it is necessary to re-shape the IT strategy – still aligned with the company strategy but no more a niche player. Our understanding is, that the IT strategy need to reflect the business strategy and vice versa leading to a digitalized IT strategy that becomes a driver of the business and its value. This will affect the traditional domains of a company such as marketing, sales and production as it is important to overcome the disjointed views of IT and digitalization to gain the full value and benefit of this new era. As outlined, the digitalization will have an impact on the IT organization, the structures and processes. It will change the patterns of collaboration as well as the necessary knowledge the IT staff need to have. Finally we believe that IT needs to be anchored in the core decision making body of a company to drive the company strategy with key impulses from the digital era.

FURTHER RESEARCH DIRECTIONS

Even though we may have the feeling that we have dealt with digitalization for ages it is a rather new phenomenon to the business and we are just at the starting point of this transition journey. Therefore, our chapter outlines the levels, dimensions and elements that affects the corporate IT but one important questions for the future is how to orchestrate the new level of agility and ever changing requirements for an IT organization. We believe, that it deserves an in-depth analysis how these “digital-dynamics” affect the IT organization, how these novelties interfere with the existing organization and how to best balance novelty, agility and tradition to create the best out of the digitalization.

KEY TERMS AND DEFINITIONS

ALM: Application lifecycle management (ALM) is the supervision of a software application from its initial planning through retirement. It also refers to how changes to an application are documented and tracked.

Big Data: Big data is high-volume, high-velocity and/or high-variety information assets that demand cost-effective, innovative forms of information processing that enable enhanced insight, decision making, and process automation.

Cloud: Describes the locations where services are acquired and data is stored, can take various forms.

Cloud Computing: Cloud computing is a general term for the delivery of hosted services over the Internet. Cloud computing enables companies to consume compute resources as a utility -- just like electricity -- rather than having to build and maintain computing infrastructures in-house.

Deployment Models: A cloud deployment model represents a specific type of cloud environment, primarily distinguished by ownership, size, and access. There are four common cloud deployment models: Public Clouds; Community Clouds; Private Clouds; and Hybrid Clouds.

Digitalization: Integration of digital technologies into everyday life by the digitization of everything that can be digitized.

Hybrid IT Infrastructure: Approach to enterprise computing in which an organization provides and manages some information technology (IT) resources in-house but uses cloud-based services for others. A hybrid approach allows an enterprise to maintain a centralized approach to IT governance, while dealing with cloud computing.

Economics of Scale: Economies of scale is the cost advantage that arises with increased output of a product. Economies of scale arise because of the inverse relationship between the quantity produced and per-unit fixed costs; i.e. the greater the quantity of a good produced, the lower the per-unit fixed cost because these costs are spread out over a larger number of goods. Economies of scale may also reduce variable costs per unit because of operational efficiencies and synergies. Economies of scale can be classified into two main types: Internal – arising from within the company; and External – arising from extraneous factors such as industry size.

Industry 4.0: Industry 4.0 or the fourth industrial revolution, is the current trend of automation and data exchange in manufacturing technologies. It includes cyber-physical systems, the Internet of things and cloud computing.

Infrastructure-as-a-Service (IaaS): Infrastructure as a Service (IaaS) is a form of cloud computing that provides virtualized computing resources over the Internet.

Internet of Things: A network comprised of physical objects capable of gathering and sharing electronic information. The Internet of Things includes a wide variety of “smart” devices, from industrial machines that transmit data about the production process to sensors that track information about the human body. Often, these devices use Internet Protocol (IP), the same protocol that identifies computers over the world wide web and allows them to communicate with one another.

Master Data Management: Master data management (MDM) is a comprehensive method of enabling an enterprise to link all of its critical data to one file, called a master file that provides a common point of reference.

Omni-Channel: Omni-channel is a multichannel approach to sales that seeks to provide the customer with a seamless shopping experience whether the customer is shopping online from a desktop or mobile device, by telephone or in a bricks and mortar store.

On Premise: On-premises is a type of software delivery model that is installed and operated from a customer’s in-house server and computing infrastructure. It utilizes an organization’s native computing resources and requires only a licensed or purchased copy of software from an independent software vendor.

Platform-as-a-Service (PaaS): Platform as a service (PaaS) is a cloud computing model that delivers applications over the Internet.

Predictive Analytics: Predictive analytics is the branch of data mining concerned with the prediction of future probabilities and trends.

The central element of predictive analytics is the predictor, a variable that can be measured for an individual or other entity to predict future behavior.

Process Re-Engineering: Documenting, analyzing, and comparing a process to benchmarks such as best-in-class practices, implementing the required changes, or installing a different process.

Public Cloud: A public cloud is one based on the standard cloud computing model, in which a service provider makes resources, such as applications and storage, available to the general public over the Internet.

Shared Service Center: A shared services center – a center for shared services in an organization – is the entity responsible for the execution and the handling of specific operational tasks, such as accounting, human resources, payroll, IT, legal, compliance, purchasing, security. The shared services center is often a spin-off of the corporate services to separate all operational type of tasks from the corporate headquarters, which has to focus on a leadership and corporate governance type of role.

Service Level Agreements (SLAs): Contract between a service provider and a customer, it details the nature, quality, and scope of the service to be provided.

Service-Oriented Architecture (SOA): Service-oriented architecture (SOA) is an approach used to create an architecture based upon the use of services. It carries out function, such as producing data, validating a customer, or providing simple analytical services.

Software-as-a-Service (SaaS): Software as a service (SaaS) is a software distribution model in which a third-party provider hosts applications and makes them available to customers over the Internet.

The Main Concepts Behind the Dematerialization of Business Processes

Liliana Ávila

Leonor Teixeira

University of Aveiro, Portugal

INTRODUCTION

Currently, Information and Communication Technologies (ICTs) represent an important tool for all the organizations that intend to improve their performance through a better management of their information processes. The dematerialization of business processes emerges as one solution that promotes a clear, structured and transparent process, especially when the problems are associated with the existence of documentation in a paper format. It comprises a range of practices, such as electronic document management, workflow management and reengineering of business processes, aiming the elimination of inefficiencies caused by the circulation of information in paper format, as well as the elimination of resources associated with the maintenance and retrieval of information in that format. The increase in productivity that often is expected to result with dematerialization of business processes comes from the (i) decrease in the amount of time to perform the tasks, (ii) effectiveness of human resources allocated to those tasks, (iii) quick access to information, and also (iv) improvement of communication flow between different services.

The dematerialization of business processes is not a new concept. It is already implemented in different areas, particularly in the public sector. However, due the lack of a theoretical framework, each organization makes its own interpretation of the concept and adopts its own methodologies and technologies. In this context, it is very important

to clarify the concept of dematerialization of business processes in order to achieve a common understanding.

This chapter aims to contribute to this knowledge domain, providing an overview of the main concepts behind the dematerialization of business processes, giving special attention to the vital role of ICTs, through the analysis of some tools that can be used to support the dematerialization of business processes. In this way, the main goal is to help organizations understanding the benefits and commitments that can arise from the modernization of their processes.

INTRODUCING THE DEMATERIALIZATION OF BUSINESS PROCESSES

The dematerialization of business processes is a relatively new concept in the domain of scientific research. Nevertheless, it is possible to find evidences of its implementation, namely in the public sector through the topic known as “e-governance”.

Usually, the concept of dematerialization can be defined as the process of scanning paper documents to obtain electronic documents, in order to eliminate the circulation of paper. According to Siatiras (2004), currently the information is probably one of the most important assets in the organizations, and therefore its efficient management is very important.

However, the dematerialization of business processes is not limited to scanning and managing documents, it also allows the organization to manage its workflows. In this sense, the dematerialization of business processes refers to the optimization of information circuits through technological applications, where the information is communicated and stored in digital format in order to expedite and facilitate the monitoring of processes, always ensuring the legal value of those electronic documents (Ávila, Teixeira, & Almeida, in press). The main gains associated with the dematerialization of business processes are the facility in search documents (Ashby, 2011; Schnitzer, 2010; Want, 2009), and the concurrent access by multiple users to the same document regardless their geographic location (Ashby, 2011; Downing, 2006). This is even more important for organizations that are active in different locations and need to exchange information in a regular basis.

The dematerialization of business processes can also be a mean to improve customer service, since the information is readily available on the computer without the need for search in paper files, allowing an immediate response to customer requests and a greater flexibility to respond to a variety of needs (Burns, 2009; Downing, 2006; Medina & Fenner, 2005). Other consequences are the savings in time and costs (Johnston & Bowen, 2005; Schnitzer, 2010; Want, 2009) and the improvement in the quality of processes and their outcomes (Ashby, 2011; Johnston & Bowen, 2005). At the human resources level, it can encourage greater communication and collaboration between people, creating a more harmonious work environment (Ashby, 2011; Siatiras, 2004; Want, 2009).

Despite the benefits pointed to a project of dematerialization of business processes, it should be noted that this type of project requires some efforts to understand and manage the factors (difficulties), arising from the implementation of

this type of projects. One of the most prevalent factors is the time of a transition to a dematerialized environment. The implementation of a dematerialization project must be preceded by a comprehensive and detailed planning process. The transition should be progressive, because it is a slow and gradual process, along which there are a large number of small steps that should be performed (Ashby, 2011; Burns, 2009). In addition, the large investment required in the initial phase (software, scanners and, eventually, new computers) and the resistance of some employees to change, should be considered. The existence of some instability feelings among workers due to the possible feeling of greater control by the managers (Downing, 2006; Medina & Fenner, 2005) may also appear as a result of the dematerialization of business processes, often seen as an obstacle to its acceptance.

Organizations must understand that the dematerialization of their business processes may involve significant organizational changes, so its implementation should not be motivated by the simple desire for eliminate the use of paper and be environmentally friendly (Ashby, 2011). Thus, the dematerialization of business processes is a complex concept emerging from the interception of other related concepts that have been more explored in the literature such as the electronic documents management, the workflow management and the reengineering of business processes. The use of ICTs is common to all these domains, playing a determinant role in the implementation of the dematerialization of business processes, justifying the greater emphasis on this topic (Figure 1).

In the following section, we will present the concepts in order to discuss in which extent they are related with the main topic that is been analysed in this chapter, i.e. with dematerialization of business processes.

Figure 1. Main concepts behind the dematerialization of business processes

THE MAIN CONCEPTS BEHIND THE DEMATERIALIZATION OF BUSINESS PROCESSES

Electronic Documents Management: Welcome to the Digital Era

The concept of electronic document management describes the tools and processes associated with managing documents and records in digital format, allowing the decrease of some risks, such as the time spending searching the required information and the use of some outdated or incomplete data (Siatiras, 2004). Thus, an electronic document management system represents the software used to manage unstructured information like emails, images, spreadsheets or text in a controlled and consistent manner.

In the scientific literature, some authors list several features related to this type of systems. These authors highlight the fact that there is a central repository for all the electronic documents, the ability to search through this repository and the control of multiple versions of a single document.

The implementation of such systems could also be a great opportunity to define and establish a common vocabulary in the organization, a consistent terminology to describe the information, instead of each person having its own way to attribute names to documents (Al Qady & Kandil, 2013).

In this “digital” context, it is very important the existence of good security protocols to protect individual rights to access and edit documents as well as define retention and automatic deletion policies, standardized classification structures and audit trails. The use of digital documents implies the existence of user access control methods for the authentication as a substitute of the traditional signature in order to assure the system integrity, authenticity, non-repudiation and notarization (Lee, 2013). Any document can be accessed remotely from any computer through a secure virtual private network connection (Wisniewski, Pummer, & Krenzelo, 2010). Other important factors that can be found in the literature and can contribute to the success of this type of project are the management support (Alzubi, 2015; Cho, 2008; Haug, 2012), the concerns with user acceptance (Cho, 2008;

Hung, Tang, Chang, & Ke, 2009), which could be mitigated for example through the definition of reward systems and training activities, as well as the external support from a consultant and the selection of software (Hung et al., 2009).

It is noted that the empirical work that have been conducted in this field focus mainly the application of electronic documents management systems in three different types of organizations: governmental entities (Afonso, Schwarz, Roldán, & Franco, 2015; Hung et al., 2009), healthcare organizations (Harmsen, 2007; Schmidt, Simmons, Grimm, Middlebrooks, & Changchien, 2006; Wisniewski et al., 2010) and companies acting in the construction sector (Al Qady & Kandil, 2013; Hjelt & Björk, 2007).

Workflow Management Systems: Performing Tasks at the Right Moment

Mentzas, Halaris, & Kavadias (2001) and Hollingsworth (1995) define workflow as a set of tasks organized to perform a business process. In its turn, a task can be performed by one or more software systems and carried out by one or more employees. Moreover, a workflow defines the order or the conditions on which a task should be executed, its synchronization and information flow. Therefore, the workflow technology enables an organization to automate their business processes more efficiently. A workflow technology distributes work items by users, indicates how the task should be performed, tracks the progress of the work item throughout the process, and generates statistics on how different steps are carried out. According to Aalst & Hee (2009), a workflow management system is a generic software package that supports the management of business processes, taking into account its information logistics. Such systems ensure that the right information is given to the right person, at the appropriate time.

Generically, workflow management systems can be characterized as supporting three levels – the business process definition, its monitoring and

the interaction with users or applications and Information Technology (IT) tools (Hollingsworth, 1995). Figure 2 illustrates how these three levels are related with each other.

According to the author, the first level relates to the build time functions, which have as main output the computerized definition of the business process. The process is translated from the real world into a formal definition, readable by computer, through the use of one or more analytical techniques, modelling and definition tools. The process design and definition usually includes a set of activities, related tasks performed by computer or people, and rules that guide the progression of the process throughout those tasks. The description of the process may be expressed in a textual or graphical language based on a defined notation. The other two levels are related to the run time. One of them consists of the process control activities. The process definition is processed by the software that schedules the several steps to perform the activities constituting that process, invoking the human resources and applications involved in each activity. The third level represents the interaction with users and IT applications in order to perform tasks.

The description provided by Hollingsworth (1995) helps to understand the benefits arising from the integration of the electronic documents management with the workflow management, representing the benefits from the adoption of the dematerialization of business processes. However, that approach can be more fruitful when combined with the reengineering of business processes. The next section presents reengineering as a tool that can be used to achieve better results.

Reengineering as a Way to Achieve Better Results

Hammer & Champy (1993), experts in the field of reengineering, define this concept as the rethinking and redesigning of business processes, in order to achieve significant improvements in key performance indicators (KPI), such as costs, quality,

Figure 2. Characteristics of workflow systems

Source: Adapted from Hollingsworth, 1995

service and speed. Achieving this goal usually requires the implementation of deep changes and abandoning all pre-established procedures in the organization (Attaran, 2004; Aversano, Canfora, De Lucia, & Gallucci, 2002; Weerakkody, Janssen, & Dwivedi, 2011). Weerakkody et al. (2011) refer that the first projects developed in this domain had a large failure rate and that the reengineering of business processes is often criticized by its radical approach. Nevertheless, these authors concluded that only the accumulation of small improvements will not result in significant changes in the organization, so if the organization really wants that to happen, it is essential to start with a more radical step, such as the business process reengineering suggests.

Limam Mansar & Reijers (2007) present a framework for the reengineering of business processes implementation composed by six main components: customers, products, business process, organization structure and population, technology and information. The proposed framework shows

how BPR implementation may involve a deep understanding of how the organization works in order to achieve significant changes and benefits. Information is identified by these authors as one of the most important components because it refers to an area where very large improvements can be made using business process redesign (BPR), either through using technology or not. It was considered the second most important component by practitioners, only behind customers.

The reengineering of business processes is a concept closely related to the workflow management systems (Aversano et al., 2002; Hollingsworth, 1995). These concepts are often mistaken, although they have different definitions. The term of workflow management system presented previously is in general associated with the technology used for automating business processes. Thus, a company can automate their processes without conducting its reengineering, and this can be done without the use of a workflow management system. However, it is considered that a process-oriented

approach is essential to implement a workflow management system. When such systems are implemented to support existing practices will certainly result in limited improvements. The adoption of a workflow management system can benefit from a reengineering effort and the opposite is also true (Aalst & Hee, 2009; Hollingsworth, 1995).

Attaran (2004) explores the relationship between information technology and business process reengineering. The author identifies several companies that have implemented the reengineering of business processes to a wide variety of processes such as product development, procurement or sales. The main barriers pointed by the author to its effective implementation are the misunderstanding of the concept, the lack of proper strategy, the management and Information Systems failure to change and the failing to recognize the importance of people.

The three concepts presented above contribute to the understanding of the dematerialization of business processes. However, ICTs play a vital role. Without them does not make any sense to talk about dematerialization of business processes. The next section presents the importance of these tools and analyses what are the alternatives and main features of the existing software to support such projects.

THE VITAL ROLE OF INFORMATION AND COMMUNICATION TECHNOLOGIES IN THE DEMATERIALIZATION OF BUSINESS PROCESSES

As mentioned previously, when we talk about electronic documents management, workflow management and reengineering of business processes, we are talking about processes supported by ICTs, and this is why the choice of software is frequently pointed as a critical success factor of such projects. ICTs play the main role and it is very important to ensure that the right choice

is made as a guarantee that its implementation benefits the organization as a whole, allowing improvements in terms of its performance.

Internal vs. External, Proprietary vs. Open-Source

Regarding the selection of the most appropriate software, each enterprise should evaluate its internal competencies before making a decision. If it is a big enterprise and has an IT department it can use its own resources and develop internally the ICT tool for support the dematerialization of business processes.

However, small and medium enterprises, that may not have the same resources, usually opt by other solutions, as outsourcing all or part of the development process or hiring external consultants to support their employees in the development of an ICT tool that fits the enterprise requirements. Nowadays, it is possible to find in the software market many technologies able to be adapted to different contexts requiring less efforts in terms of financial and other resources when compared with the development of a new software. In case the enterprise decides to select an alternative from those already available in the market, it can choose between proprietary and open-source software.

In the last years, there were great advances in the field of open-source software and it became an alternative increasingly sought, presenting many benefits when compared with proprietary software, namely in terms of costs, quality and customization (Chester, 2006). Although open-source software presents clear benefits, it is important to think about all the variables because in some cases savings may be illusory. According to a survey conducted by Accenture PLC in August 2010 with directors from 300 enterprises in United States and United Kingdom, 50% of respondents said to be committed to the use of open-source software, while 28% assume it as an experimentation phase and 69% expressed interest to increase the investment at this level (Collett, 2010). In the same study, when surveyed about the main benefits

of open-source, the most cited factors were quality (76%), reliability (71%), security (70%) and then the decreasing of total costs (50%).

Nagy, Yassin & Bhattacharjee (2010) identified some barriers for the adoption of open-source software and suggested some actions that can be taken in order to mitigate each one of them. They identified barriers related to knowledge, integration with different technologies, lack of code standardization, previous investment in proprietary software and lack of software maturity. To prevent these barriers, companies may, for example, provide training to their employees, define standards, consider using open-source where there are no proprietary software, define maturity models and evaluate case studies in an independent way.

The open-source software has attracting increasingly interest of researchers from Software Engineering and ICTs. Therefore, it seems relevant to explore the applicability of this type of software to the dematerialization of business processes, through the comparison of features provided by

several proprietary and open-source software solutions available in the market.

Is Open-Source A Solution for the Dematerialization of Business Processes?

In the software market is possible to find some proprietary and open-source solutions for the management of business processes which can be considered in the implementation of dematerialization business processes projects. In a previous project (Ávila, Teixeira, & Almeida, 2015) a study was conducted that aims to analyze some existing market solutions in order to identify the main features of these tools and determine if open-source constitutes an advantageous alternative when compared with proprietary software. This comparative study was only based on information accessible via the official website of the respective providers, where are only presented the most important and distinctive features. Table 1 shows the results of this study.

Table 1. Comparative study of software to support the implementation of dematerialization of business processes

Proprietary Software			Features	Open-Source Software				
[1]	[2]	[3]		[4]	[5]	[6]	[7]	[8]
•		•	<i>Design workflows with BPMN</i>	•		•		•
•			<i>Process simulation</i>			•		
•		•	<i>Process optimization</i>	•				•
•		•	<i>Model repository</i>	•		•		
•	•	•	<i>Web forms designer</i>			•		•
•		•	<i>Client-server architecture</i>		•	•	•	
•		•	<i>Software in the cloud</i>	•				•
•			<i>Notifications</i>		•		•	
•		•	<i>Monitoring activities</i>	•				
	•	•	<i>Management users</i>	•		•	•	•
•	•	•	<i>Reports</i>	•		•	•	
	•		<i>Digital signature</i>				•	
•			<i>Collaboration tools</i>		•	•		

Label: [1] Appian; [2] FileDoc; [3] RunMyProcess; [4] Activiti; [5] Alfresco; [6] Bonita Open Solution; [7] iPortalDoc; [8] ProcessMaker

Analyzing Table 1, it is possible to conclude that there are some features which are common to almost all the studied solutions, namely the possibility of manage users and the production of reports. Other features frequently offered are the design of workflows with BPMN (Business Modeling Processes Notation), the design of web forms and client-server architecture. Moreover, some of the presented solutions give more relevance to the features related to workflow management, while others give more importance to documents management, such as FileDoc and iPortalDoc. In general, and as expected, proprietary software presents a wider set of features, while open-source software is more limited. However, taking into account the advantages mentioned previously, the features offered by open-source solutions should not be ignored, namely the Activity and Bonita Open Solution.

Currently, there are companies from several sectors with proven real use cases using open-source solutions to manage their business processes. Some of them are, for example, NASA and Michelin which are clients of Alfresco or even Accenture, Cisco and several French Ministries which adopted the Bonita Open Solution. Open source technologies may also be valuable options for organizations with a small dimension which intend to implement and test the dematerialization of business processes in some of their processes.

FUTURE RESEARCH DIRECTIONS

As already mentioned, the dematerialization of business processes is a relatively unexplored concept in the literature. Therefore it is possible to identify many directions for future research. First, it seems important to find a common definition of what the dematerialization of business processes is, reflecting the vision of academics and practitioners. Academics can contribute producing case studies of organizations that have experienced the dematerialization of business processes and identifying the best practices in this domain, covering

organizations with different dimensions and from different sectors.

Moreover, this approach to administrative modernization seems to be more popular among the public sector and less notorious in the private sector. Defining a more consistent methodology could be very useful to support organizations in general, regardless the sector they belong to.

Finally, it could be relevant in future research explore the best practices to accelerate the implementation of the dematerialization of business processes in a cost-effective way for companies, in order to make possible for any organization take advantage from this approach to manage their information flows. One suggestion is evaluating the potential use of open-source technologies in a cloud computing paradigm. Currently, the popularity of these technological solutions represents a good option for organizations, allowing them to reduce the initial investment and also offering advantages in terms of mobility and collaboration. Therefore, cloud computing can be a good ally to the dematerialization of business processes.

CONCLUSION

The main purpose of this chapter was to clarify what the dematerialization of business processes is through the presentation of the main concepts behind it, and which in turn are further explored in the literature.

First, the electronic documents management, the workflow management and the reengineering of business processes topics were briefly introduced. After that, a great emphasis was given to the vital role of ICTs. It was conducted a comparative study in order to evaluate in which extent open-source software could be a good option for the implementation of the dematerialization of business processes with a lower cost for organizations. Regarding the technological offers available in the market, it is concluded that, although the proprietary solutions are the most comprehensive, open-source technologies

now occupy a prominent position, because they offer a set of features that responds to the needs of most organizations looking for new approaches to the production, organization, movement and retrieval of information based on the redefinition of its processes and information circuits.

With this chapter, it is intend to present the dematerialization of business processes as a good solution for problems related to the existence of documents in paper format, which are common to most organizations, enabling the improvement of its performance by managing their workflows. This chapter can give a significant theoretical contribution to this study area, although we believe that there are still many possible directions to explore more about the dematerialization of business processes once it is an approach that integrates the contribution of other knowledge domains.

KEY TERMS AND DEFINITIONS

Dematerialization of Business Processes: The management of processes through an information system that allows simultaneously the workflow and electronic documents management.

Electronic Documents Management: The management of documents that exist in a digital format.

Information and Communication Technologies: Tools used to support information sharing and communication in a digital world.

Open-Source Software: A software developed by a group of volunteers and which source code is available for anyone, who can modify or improve it.

Proprietary Software: A close source software, licensed under exclusive legal right of the copyright holder.

Reengineering of Business Processes: A total redefinition of processes in order to improve significantly their results.

Workflow Management System: A system that controls the execution of tasks by different actors in order to complete a process with the desire output, in the right time.

Scanning for Blind Spots

B

Barbara Jane Holland
Brooklyn Public Library, USA

INTRODUCTION

Many research studies indicate that when reality and conviction are at odds with each other conviction often win. Companies and nonprofit organizations are often blindsided when faced with demographic, political, environmental, technological changes and new rivals. The most talented and best prepared leaders face complex, ever-changing, and often unpredictable challenges. The more an organization utilizes a systemic approach, the more likely they will avoid blind spots. Environmental Scanning or ES, provides a view of community needs by detecting pertinent economic, social, cultural, environmental, health, technological and political trends, situations and events.

Frank Aguilar's classic book "Scanning the Business Environment", exemplify some of the factors involved in determining what external information is strategic or relevant. The managers studied by Aguilar were mainly interested in the news of the market, including competitors, customers, pricing, market structure and change...

To be effective in a complex and changing world, decision makers must look ahead to anticipate emerging trends, issues, opportunities, and threats. Developing and applying strategic foresight must come into play. A well conducted scan results in a new management and marketing style that is more forward thinking. Scanning has long been standard practice in the military, the intelligence community, and the business world and is a core method in futures research. In recent

Figure 1. Environmental scanning

DOI: 10.4018/978-1-5225-2255-3.ch077

years, horizon scanning has been used in a growing number of fields in the public sector, such as human health (Douw and Vondeling 2006) and education (Munck and McConnell 2009). This chapter defines environmental scanning, examines Blind spots, weak signals, and effective tools used for discovering emerging trends beneficial to a company's or organization's strategic planning.

BACKGROUND

The lack of diversity in information sources may contribute to blind spots in environmental scanning. If organizations get their information from acceptable, conservative or authoritative sources, they may not see the changes taking place in their external environment. A large amount of pertinent information comes from face to face discussions, rumor, gossip and conjecture.

Moreover, it keeps the organization informed of current trends and challenges of the future.

Companies find it demanding to identify and include basic signals about their future developments and challenges in their existing, and often static strategic planning processes. Environmental scanning helps corporations, and nonprofits to understand external threats and opportunities leading to change. When an organization has undergone significant changes the knowledge discovered by an environment scan is intrinsic.

Aguilar (1967), in his study of the information gathering practices of managers, defined scanning as the systematic collection of external information in order to (1) lessen the randomness of information flowing into the organization and (2) provide early warnings for managers of changing external conditions.

Research suggests that effective scanning and planning is linked to improved organizational learning and performance (Choo 2002).

Environmental scanning practiced by different Japanese and Korean corporations share a surprisingly common pattern as observed in a 1988 study

by Ghoshal). Information gathering is typically achieved through six channels and sources:

- The planning division,
- Individual specialists,
- Patent department,
- Advisory boards,
- Individual employees, and
- Technology attaches.

ENVIRONMENTAL SCANNING AND THE CORPORATE ENVIRONMENT

Environmental scanning practiced by various Japanese corporations share a common pattern. The same similarity has been observed in large South Korean corporations (Ghoshal 1988).

Japan owe much of its success to trading companies after world war II. Their corporate culture is based on gathering information from trade magazines, newspapers and business associates. Raw information is collected daily and transmitted overseas to the Japanese trading company called Sogo Shosha. A senior intelligence staff collates and shapes this information and submits it to key policy makers within the trading company. The Sogo Shosha have become masters at collecting business intelligence, tapping into the most public, boring sources, cultivating open human contacts.

A major task in any strategic planning process is thus to challenge existing perceptions and to identify blind spots as well as weak signals in order to effectively and efficiently detect future chances and risks at an early stage. Existing tools for identifying future changes that a company might face, such as operative forecasting or strategic forecasting, are generally not able to perform this task very well. Blind spots can be described as developments that a company knowingly or unknowingly overlooks while weak signals can be described as first indicators for future changes in the environment.

Figure 2. Blindspot analysis chart

Blind spots are commonly caused by an individual's or organization's psychological filtering of incoming data flow from economic and industry analysis when determining strategic decisions. The presence of blind spots within an organization becomes apparent when one of the following occurs:

1. Firm is unaware of a pending strategic development
2. Firm is aware, but misinterprets the strategic development
3. Firm correctly perceives the strategic development, but is too slow to react.

ANALYTICAL TOOLS AND DETECTING BLIND SPOTS

Blind spots may prevent an organization from recognizing a problem or enacting a solution.

Identifying and communicating the blind spots acknowledges their existence and power. People may still choose to support their blind spot while understanding the risks.

Originally conceived by Michael Porter and Developed by Benjamin Gilad, blind spot analysis attempts to identify and improve flaws, assumptions and inaccuracies that adversely affect strategies and decisions. SWOT analysis, although widely used and misused is to assess the current situation of an organization, department, program or strategy.

DEFINING THE ISSUE TO BE ANALYZED

Example: Libraries should use drones to improve outreach by delivering resources to the geographically isolated or homebound and providing deposit collections to disaster areas. In addition to con-

Table 1. Analyzing blindspots

Invalid Assumption	Winners Curse	Escalating Commitment	Constrained Perspective	Over Confidence	Information Filtering	Educated Incapacity
organizational Myths Unchecked Facts	Overpayment to achieve objectives	Pride/Fear Prevents Loss Cutting	Over estimate risks	Over estimate expertise and knowledge	Misinterpretation of Information	Experience created bias

Figure 3. Blindspot matrix

necting researchers via video equipped drones, and lending library books on a 24 hour basis. This may be analyzed using a blind spot analysis and SWOT analysis.

SWOT Analysis was originated by Albert S Humphrey in the 1960s, the tool is as useful now as it was then. You can use it in two ways – as

a simple icebreaker helping people get together to “kick off” strategy formulation, or in a more sophisticated way as a serious strategy tool. Strengths and weaknesses are often internal to your organization, while opportunities and threats generally relate to external factors.

Figure 4. SWOT analysis chart

Table 2. SWOT analysis

Strengths	Weaknesses
1.Strength One	1.Weakness One
2.Strength Two	2.Weakness Two
3.Strength Three	3.Weakness Three
Opportunities	Threats
1.Opportunity One	1.Threat One
2.Opportunity Two	2.Threat Two
3.Opportunity Three	3. Threat Three

After using SWOT and Blind spot Analysis to define the problem and consider solutions then create action plans to mitigate the risks.

WHAT ELSE SHOULD YOU BE LOOKING FOR?

TOWS Analysis is a variant of the classic business tool, SWOT Analysis. The only difference between TOWS and SWOT is that TOWS emphasizes the external environment while SWOT emphasizes the internal environment. SWOT or TOWS analysis helps you get a better understanding of the strategic choices that you face.

It helps you ask, and answer, the following questions: How do you:

- Make the most of your strengths?
- Circumvent your weaknesses?
- Capitalize on your opportunities?
- Next step of analysis, usually associated with the externally-focused TOWS Matrix, helps you think about the options that you could pursue. To do this you match external opportunities and threats with your internal strengths and weaknesses.

SPOTTING AND INTERPRETING TRENDS

Trends are developments in the environment of an organization and multiple events in a particular direction. It is the pattern that counts. Early warnings and signals are usually swept off the table unless you have proof and data to support it.

Scanning will result in a repository of trends that you and your scanning team think might be important to your organization's future. The next stage in your scanning process is to interpret your trends. This work is best done as a group by your scanning team. During this process scanners explore trends might evolve over time. Spotting a trend as an individual, can be risky. Moreover, you most likely will not be given the credit you deserve and may be terminated for pointing out

Table 3. Risk mitigation plan

RISK	Severity	Probability	Warning Signs	Plan
Summarize the risk	Low/medium/high	Low/medium/high	Identify the signals that warn you when risks are occurring	Create potential solutions to mitigate the risk

Table 4. SWOT worksheet

Strengths What do you do well? What unique resources can you draw on? What do others see as your strengths?	Weaknesses What could you improve? Where do you have fewer resources than others? What are others likely to see as weaknesses?
Opportunities What opportunities are open to you? What trends could you take advantage of? How can you turn your strengths into opportunities?	Threats What threats could harm you? What is your competition doing? What threats do your weaknesses expose you to?

Figure 5. TOWS matrix

Internal Factors External Factors	Strengths (S)	Weaknesses (W)
	SO Strategies Generate strategies here that use strengths to take advantage of opportunities	WO Strategies Generate strategies here that take advantage of opportunities by overcoming weaknesses
Opportunities (O)		
Threats (T)	ST Strategies Generate strategies here that use strengths to avoid threats	WT Strategies Generate strategies here that use minimize weaknesses and avoid threats

Table 5. 2TOWS strategic alternatives worksheet

	External Opportunities(O) 1. 2. 3. 4.	External Threats (T) 1. 2. 3. 4.
Internal Strengths (S) 1. 2. 3. 4.	SO	ST
Internal Weaknesses (W) 1. 2. 3. 4.	WO	WT

new developments which are in stark contrasts with the official view (de Rujiter 2014). Most trend reports are one sided. They report about globalization and ignore a growing trend of anti-counter globalization. Counter-trends are more interesting. Counter-trends are full of insights and are many times the bases of real foresights.

Once you come up with a new trend, finding the data to support it is the most difficult task. The data has to be named and captured to support the trend.

MAJOR ISSUES, DRAWBACKS AND LIMITATIONS

Scanning may not always be effective in an organization. The volume of information can be so overwhelming resulting information overload. Pieces of information may be overlooked and or missed. There are many sources of information that scanners are not be aware of missing information that's pertinent. Information may not have been gathered in a timely manner. Furthermore, determining if the information is relevant, familiarity with the topic and information sources language

Figure 6. Scanning and forecasting chart

usage, all play a role in the analysis process. Environmental uncertainty can lead to misjudgments.

Judging the appropriate level of resources to devote to environmental scanning is difficult. Where environmental conditions are turbulent and full of potentially significant changes, large amounts of resources may be justified. Even with large efforts, there is no guarantee that some wholly-unanticipated event will cause serious problems or present a great opportunity for which you aren't prepared. More importantly, the interpretation of trend information and forecasting is an inexact science at best. The farther into the future a scan probes, the more cautious you must be with the interpretation. Blind spots and Group think must be avoided.

AVOIDING BLIND SPOTS AND GROUPTHINK

All organizations have blind spots. Groupthink is a cognitive dissonance on a collective level. It forces everyone in a group to think the same. It can be useful for visioning and alignment. On the other hand it can make an organization blind, especially if there is an dominate leader or extremely strong peer pressure to think alike. It's not enough to spot the trend but also be alert to the prevailing organizational perspective. It is better to use outsiders as they are not affected

by company blindness. They are allowed to say things that insiders can't. Managers have instinctive attitudes and assumptions about the external environment. They usually pay attention to what's most immediate, namely their industry sector and environments. They may have blind-spots which ignore or discount certain market sector trends (Pitt 2012).

Active and open exploration of communities incorporating diverse sources of information and viewpoints are keys to successful scanning. When organizations utilize a systemic approach, they are more likely to avoid blind spots while scanning.

You may not be given credit for noticing important trends. Being too blunt might get you fired for pointing out new developments which are in stark contrast to the official view. Spotting trends is not enough but you must also be alert to the prevailing organizational perspective (Rujiter 2014).

Understanding the institutional frame of reference with help you locate the blind spots and simultaneously make you aware of potential resistance you'll need to overcome to get your point across. Here, it is best to use outsiders. They are not affected by company blindness and cannot be fired. They are allowed to say what insiders cannot. The outside view can stretch the company mindset. Outsiders can lightened all the blind spots..

SOLUTIONS AND RECOMMENDATIONS

Emerging issues start with a value shift, or a change in how an issue is viewed. An opinion leader or champion inevitably emerges to move the issue into the public view. It is at this time that the emerging issue can be identified.

Leaders often are forced to make decisions with flawed or incomplete information and, more importantly, often don't know that is the case—creating blind spots. One way of avoiding blind spots is to create a culture within a company that promotes straight talk about problems and concerns. Developing peripheral vision can help alleviate blind spots.

- **De-Emphasize the Hierarchy:** Break tradition when in the process of problem-solving on broad organizational issues, skip level down into the organization and gain new perspectives. Just be sure to let your management team know that you're going to be doing it, so that they don't overreact.
- **Discourage Group Think:** Rather, promote speaking for one's self. Whenever you hear someone on your management team begin a sentence with something like, "I think we all believe..." it is quite possible that you have fallen into some form of groupthink.
- **Create Recognition Opportunities:** By establishing mechanisms that foster ways for individuals or work units to be recognized for "out of the box" thinking, a leader can begin to change the very culture that has inadvertently muted the growth potential of a business.

TEAM MEMBERS AS OBJECTS OF STUDY

Get to know your team in depth in order to interpret the subtleties of their behavior. Knowing how to read team members means not only being aware

of their tendencies but also of any deviations from their typical approach. For example, if an individual who is inclined to examine every side of an issue before making a decision suddenly appears to see only one side of an argument, you need to understand why that is.

PAY ATTENTION TO BEHAVIORAL RED FLAGS

Be aware of subtle clues that may suggest people are not expressing what they really think

Warning signals you should watch for:

- Nonverbal behaviors, such as eye rolling.
- Omissions, which are the important areas that are simply not surfaced or discussed.
- Silence, which may indicate an unwillingness to take a contrary position.
- Non-answers, such as when an individual is obviously being intentionally evasive.

When you scan the environment you should interview and talk to people in and out of your organization. Aim to talk to people that have different approaches and perspectives.\

FUTURE RESEARCH DIRECTIONS EXAMINED

Desk Research

A sensible way to research backgrounds and facts when you want to map the outside world. When conducting Desk Research, you are looking for signals about future. Many times the amount of research has already been done with desk research. Other sources can be used besides the internet such as reference books, newspapers, magazines, and annual reports. The advantages of Desk Research you can work from your office, you do not need other people and it focuses on facts. RSS feeds can used this way to support this way of environmental scanning.

The Disadvantage of Desk Research

Test may be outdated. You cannot allow yourself to be guided by data of the past. You may run the risk of losing yourself in time-consuming theoretical studies in which you have only consulted a few people. By involving several people in your scan of the environment, you create ownership in a broader group thereby raising support for the project.

Currently, with the help of a DESTEP analysis organizations may easily get the overview of its external environment. Each and every company is faced with some factors they cannot exercise influence on and the factors they can exert influence on. The DESTEP theory mainly represents the Demographic, Economic, Social/ Cultural, Technological, Economic and Political factors. These factors may directly or indirectly influence the organization's operations and clarifies how a company can adjust their strategy with such macro-economic factors.

Horizon Scanning

Horizon scanning, a term frequently applied to futures scanning is frequently based on desk research, helping to develop the big picture behind the issues to be examined. This is scanning at the periphery, at the edges of current thinking, looking for emerging issues, threats and opportunities. Also known as environmental scanning, external scanning, and strategic scanning, horizon scanning may also be defined as "the acquisition and use of information about events, trends and relationships in an organization's external environment, which would assist management in planning the organization's future course of action. Effective horizon scanning serves as an early warning system to identify potential opportunities and threats, enable decision makers to plan accordingly and take timely action, and foster a culture of foresight throughout an organization.

The goals are to find emerging indications of important future developments so decision makers

can plan accordingly and take action quickly and more broadly to foster a culture of foresight in the organization. Some horizon scanning projects and systems fail to meet expectations or achieve goals, for a variety of reasons such as insufficient budget, lack of management support, and weak stakeholder participation. An overabundance of raw data and techniques to make sense of the data is not progressing fast enough.

The Foresight Process

The foresight process is to gather insightful information on potential futures, develop future scenarios, and action plans in the event that one of scenarios unfold. When participants in the foresight process are all have similar knowledge and attitudes towards trends, and developments, they are prone to develop monotonic scenarios.

Foresight, traditionally have involved only a limited number of top level decision makers from the organization. As a rule, internal players have been assigned to scan the environment, gather external and internal information, processing it into forecasts, and presenting it to top management. This procedure provides top management with information that facilitates decision making on current and new business development in general and innovation activities. Many companies discover that opening this process can identify new trends, business opportunities and detect potential blind spots.

Open Foresight workshops enable the company to learn about weak signals.. When managers recognize weak signals, they can identify new business opportunities.

See Tables 6, 7, and 8

TREND WATCHERS AND FUTURE OPPORTUNITIES

Trends, are interlinked and connected to socioeconomic and cultural drivers influencing tomorrow's government and business success stories. Trends

Table 6. Foresight methods by type of technique

help you find the right insight or opportunity, generate the right ideas, and then execute them in the right way. The result is happy consumers. The difference between a trend and a fad is when trends emerge and external change unlocks new ways to serve age-old human needs and desires. There's the expectation that the instant connection and social gratification available online will be a part of offline social lives, too. This is a trend. Then you have to consider is the service a fad, or will young urbanites still be swiping furiously in 2035? The question is not important: trends aren't about the success or failure of individual

innovations but will consumer desire for instant connection and social gratification continue?

Trend watchers understand that if they rely *only* on conventional market research they'll risk missing powerful *future* opportunities. Today trend watchers use a network of spotters who send hundreds of local innovation examples every month. They allow a unique window on global consumerism as it evolves week by week, month by month. consumerism as it evolves week by week, month by month. These insights can help companies such as Trendwatching.com spot new trends, or help us update existing trends.

Kjaer Global, is a leading international trend forecasting consultancy helping companies navigate the future. They specialize in Trend Management – strategic platforms and trend tools such as a Trend Atlas, to enable the development of 'future proof' concepts for people centric products and services. Their forecasts include, by 2020 the focus will be on prevention rather than healing. Cloud health intelligence will evolve, as apps, mobile diagnostics and intuitive biofeedback become

accessible resources in our daily lives. Printing your own medicine will become available. Gender equality will be crucial. Two thirds of graduates in advanced economies will be women majoring in business.

CONCLUSION

There are many advantages to environmental scanning in modern organizations. Environmental scanning assists in the development of strategic plans and policies, the assessment of new information, and the adjustment of internal operations to meet new challenges as they arise. It can identify an organization's unique strengths, locate weaknesses in its competitors, and identify new markets, prospective customers, and emerging technologies..

Despite the advantages of environmental scanning, it is not widely used in companies as might be suggested in academic publications on the subject. Although scanning is challenging, it is also necessary. Bringing diverse stakeholders together in participatory scanning is also challenging. Identifying blind spots and weak signals of change in a complex, turbulent environment is like looking for a sewing needle on plush rug. Separating meaningful signals from all the noise requires the rare ability to see beyond prevailing mindsets and paradigms. Analyzing and correctly interpreting potential signals of change calls for creativity and insight. Acting on possible opportunities and threats presented by an early change demands visionary leadership and careful strategy. Successfully achieving all of these requirements is indeed difficult. Scanning can enhance discussion about future-oriented issues within an organization, as well as help decision makers anticipate and quickly respond to external change. A formal horizon scanning system is a vital but often missing component in the strategic planning process of public natural resource and environmental organizations.

KEY TERMS AND DEFINITIONS

Blind Spots: Areas important information go unnoticed and thus the organization falls into one of any number of traps. These include misjudging industry boundaries, failing to identify emerging competition, falling out of touch with customers, over-emphasizing a competitor's visible competence, and allowing corporate taboos or lack of foresight to limit their frame of reference. Any one of these mistakes will prevent organizational leaders from taking advantage of the opportunities available to them.

Competitive Scanning: The objective is to understand competitors' strategic positioning in terms of sustainable development but also the way in which they are evolving.

Delphi: It is essentially the polling of experts, over a number of rounds, to generate consensus about a particular topic or issue. Delphi does not survey the outlying views or the dissenting views, but is useful where a high degree of credibility is required. The key question to ask here, as with all methods, is what image of the future is generated in this scanning output? And, whose voice is not being heard? Japan has been using a Delphi approach for many years, and produces quarterly reviews on science and technology trends.

Environmental Scanning: Defined as 'the study and interpretation of the political, economic, social and technological events and trends which influence a business, an industry or even a total market.

External Environment: Evaluation of the possible or probable effects of external forces and conditions on an organization's survival and growth strategies.

Foresight: Defined as the capacity to think systematically about the future to inform decision making today. It is a capacity that we need to develop as individuals, as organisations, and as a society.

Futures Approaches: The tools, methods and thinking styles used to build an organisational foresight capacity, usually interdisciplinary and inclusive rather than restricted to a particular method or philosophy.

Horizon Scanning: It is a term frequently applied to futures scanning. This is scanning at the periphery, at the edges of current thinking, looking for emerging issues, threats and opportunities.

Macro Environment: Major external and uncontrollable factors that influence an organization's decision making, and affect its performance and strategies. These factors include the economic factors; demographics; legal, political, and social conditions; technological changes; and natural forces.

Metascanning: There are many people and organizations whose job it is to scan the future. Some will let you have limited access to some of their findings for free, but most will ask you to sign up for a service. The value is that they have already done the initial work for you saving you time – and are satisfied with their approach and methods.

Paralysis by Analysis: The state of over analyzing.

PEST: It is an acronym that stands for Political, Economic, Social and Technological factors affecting a business decision. It is a framework used in the early phases of strategy development to describe the landscape and environment in which a firm operates.

Strategic: The decision making process whereby a strategic plan is drawn up.

Strategic Scanning: Involves looking for what are known, in the foresight profession, as “weak

signals.” and as a result, they may seem to have little or no bearing on “here and now” and may therefore not seem useful.

Strategy: Michael Porter a strategy expert and professor at Harvard Business School, emphasizes the need for strategy to define and communicate an organization’s unique position, and says that it should determine how organizational resources, skills, and competencies should be combined to create competitive advantage.

Strategic Scanning: Involves looking for what are known, as “weak signals and have little or no bearing on “here and now” and may therefore not seem useful.

Trend: A grouping of similar or related events that tends to move in a given direction, increasing or decreasing in strength of frequency of observation; usually suggests a pattern of change in a particular area (for example, consumer behaviour, technology use).

Strategic Information Systems Planning

Maria Kamariotou

University of Macedonia, Greece

Fotis Kitsios

University of Macedonia, Greece

INTRODUCTION

In this day, turbulence in the businesses' environment is on the increase. Therefore, businesses are obliged to respond to that environmental uncertainty. Information Systems (IS) and Strategic Planning support this effort. IS are connected with business strategy, management skills, decision making and aims to increase competitive advantage (Zubovich et al., 2014). Researchers have focused on the process of Strategic Information Systems Planning (SISP) since 1970. The purpose of SISP is to support the goals and the business strategy, through IS. Furthermore, SISP helps businesses to innovate, create new products, reduce costs and enhance relationships with customers (Kamariotou & Kitsios, 2015, Ullah & Lai, 2013). The process of SISP contains five phases, which are strategic awareness, situation analysis, strategy conception, strategy formulation and strategy implementation planning. These phases help businesses not only to define IS strategy but also to develop IS.

Previous studies have examined the effect of these phases on SISP success. Also, other studies have concluded that there is a positive relationship between SISP and firm performance. These surveys that have discussed the relationship between SISP and firm performance have been presented only by a theoretical approach (Goldsmit, 1991, Lederer & Sethi, 1996). These surveys collected data using questionnaires in large firms. Surveys in SMEs which constitute the main component of each economy, are limited however (Newkirk et al., 2003).

Consequently, the aim of this chapter is to propose a holistic approach in order to investigate the significance of SISP process, to highlight phases that contribute to a greater extent of success and to draw conclusions concerning the successful implementation of digital strategy in firms.

The structure of this chapter is as following: after a brief introduction to this field, a theoretical framework is analyzed on the basis of the literature review about SISP phases and success in firms. Then in the next section, the findings of previous surveys are presented, whereas the final section concludes the paper.

BACKGROUND: STRATEGIC INFORMATION SYSTEMS PLANNING AND PERFORMANCE

SISP has become a significant planning activity in organizations and a major issue for IS management. Many factors have contributed to the change of the role of IS in business in recent years. These factors involve the use of IS for competitive advantage, the effusion of IS in businesses, the involvement of IS on businesses' daily operations and the increase of interorganizational systems. Due to these changes, strategic planning for the IS function is necessary so that businesses can effectively achieve their goals in this complex and dynamic environment (Pvemkumar & King, 1991, 1994).

SISP can be defined as the ability to shape the strategy of a business and tools, techniques and

methodologies were suggested to support organizations in determining potential opportunities to deploy IS with greater competitiveness (Pepard, et al., 2014). SISP is an integrated process which includes certain phases. These phases and their activities are presented as follows. The first phase is Strategic awareness. This phase includes the identification of key planning issues, planning objectives, organizing the planning team and the encouragement of top level managers. The second phase is Situation analysis. This phase involves the analysis of current business systems, current organizational systems and current IS. Also, it includes the analysis of the current external and internal business environment and the current external Information Technology (IT) environment. Next, the third phase is Strategy conception. This phase includes the determination of main IS objectives, opportunities for improvement, alternative scenarios as well as the evaluation of opportunities for improvement. Also, it includes the definition of high level IS strategies. The next phase is Strategy formulation. In this phase, businesses select the most suitable scenario from the previous alternatives scenarios, according to new business processes and new IT architectures. Then this scenario is evaluated according to its strategic and technological impact. Also, in this phase, specific new projects and priorities for new projects are identified. These projects consist of specific activities which support the implementation of the selected scenario. The last phase is Strategy implementation planning. This phase involves approaching the actions of change management and the evaluation of strategic plan (Brown, 2004, 2010, Kamariotou & Kitsios, 2017, 2016, Kitsios & Kamariotou, 2016, Maharaj & Brown, 2015, Mentzas, 1997, Mirchandani & Lederer, 2014, Newkirk & Lederer, 2006, Newkirk, et al., 2008).

Despite the fact that previous researches have shown the success of the implementation of these phases in IS' development, many factors affect negatively the success of the process. Such important critical factors are management commitment, the involvement of employees, the

communication between the members of the team as well as the planning horizon. On the other hand, their advantages are the increase of products' quality and the effectiveness of IS (Brown, 2010, Cohen, 2008, Haki, 2011, Luftman & Brier, 1999, Pai, 2006, Silvius & Stoop, 2013, Teo, et al., 1997, Yang, et al., 2013, Zubovich, et al., 2014). Other factors which have an impact on SISP process are the analysis of the environment and the knowledge sharing (Maharaj & Brown, 2015, Pai, 2006, Yang & Pita, 2014, Yang, et al., 2013, Zubovich, et al., 2014). The determination of planning with a certain frame is very important due to technological changes which affect SISP process (Newkirk, et al., 2008).

King and Teo, (2000), argue that the factors which influence the process of SISP are the understanding of the objectives, management commitment and the creation of integrated plans. These factors impact on the firm performance of a business and especially on the index of Return on investment (ROI), as well as on the increase of market share and on customer's satisfaction. Also, Lederer and Sethi, (1991), concluded that the most important factors are related with systems' architecture, their cost and their implementation. Furthermore, they highlighted factors which are related to managers' involvement, the small horizon of projects, the support of financial plan for the development of IS, as well as knowledge sharing, analysis of business environment and understanding of strategic objectives. Earl, (1993), considered the linkage between business objectives and IS, the increase of competitive advantage through IT as well as the necessary resources for the development of IS as the major factors.

The success of SISP is defined as "the degree to which the objectives of SISP are achieved" (Pai, 2006). Several authors have measured the success of SISP with two dimensions: quality and effectiveness, while others have measured it with four, named: alignment, analysis, collaboration and capabilities (Newkirk & Lederer, 2006, Pai, 2006). A combination of the above dimensions proposed by Yang and Pita, (2014), who measure

the success of SISP with aligning business strategy and Information Systems' strategy and the effectiveness of Information Systems Design. Other researchers measure SISP success with variables such as user satisfaction, quality of information and system and organizational impact (Heo & Han, 2003). Another different approach for the measurement of the process comes from Silvius and Stoop, (2013), who suggested variables such as the alignment between business strategy with Information Systems strategy, the development of skills, the degree of management commitment and the achievement of objectives.

As for the four dimensions of SISP success, the first one includes the understanding of IS in supporting strategy, the identification of opportunities to support the strategic direction of the firm, the alignment between IS strategies with the strategic plan of the organization, the education of top management on the importance of IT and the adaption of technology to strategic change. The second dimension contains variables such as the generation of new ideas to reengineer business processes through IT, the understanding of information needs through subunits, the understanding of the dispersion of data, applications, and other technologies throughout the firm, the development of a "blueprint" which structures organizational processes, the improvement of the understanding of how the organization actually operates and the monitoring of internal business needs and the capability of IS to meet those needs. The third dimension includes the development

of clear guidelines of managerial responsibility for plan implementation, the Identification of potential sources of resistance to IS plans, the support of open lines of communication with other departments, the achievement of a general level of agreement regarding the risks/tradeoffs among system projects and the avoidance of the overlapping development of major systems. Finally, the last dimension includes capabilities such as the ability to identify key problem areas, the ability to anticipate surprises and crises, the flexibility to adapt to unanticipated changes and the ability to gain cooperation among user groups for IS plans (Newkirk & Lederer, 2006, Newkirk et al., 2003).

Table 1 summarizes the phases and the dimensions of SISP success.

Researchers have measured firm performance with variables such as sales growth, profitability, innovation, growth of customer satisfaction and growth of market share of products and services (Andersen, 2001, Bergeron et al., 2004, Chatzoglou et al., 2011, Croteau & Bergeron, 2001, King & Teo, 2000, Oh & Pinsonneault, 2007).

In Europe at about 75% of all businesses are SMEs. Although, family businesses pay attention to the business's long-term sustainability, they do not implement strategic planning (Siakas et al., 2014). Greece is a country which has plenty of SMEs comparatively to other countries of the European Union and most of them have been negatively affected from the financial crisis (Vassiliadis & Vassiliadis, 2014).

Variables	Questions	References
Alignment	Maintaining a mutual understanding with top management on the role of IS in supporting strategy	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Understanding the strategic priorities of top management	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Identifying IT-related opportunities to support the strategic direction of the firm	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Aligning IS strategies with the strategic plan of the organization	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Adapting the goals/objectives of IS to changing goals/objectives of the organization	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Educating top management on the importance of IT	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Adapting technology to strategic change	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Assessing the strategic importance of emerging technologies	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
Analysis	Identifying opportunities for internal improvement in business processes through IT	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Maintaining an understanding of changing organizational processes and procedures	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Generating new ideas to reengineer business processes through IT	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Understanding the information needs through subunits	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Understanding the dispersion of data, applications, and other technologies throughout the firm	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Development of a ‘blueprint’ which structures organizational processes	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Improved understanding of how the organization actually operates	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Monitoring of internal business needs and the capability of IS to meet those needs	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
Cooperation	Developing clear guidelines of managerial responsibility for plan implementation	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Identifying and resolving potential sources of resistance to IS plans	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Maintaining open lines of communication with other departments	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Coordinating the development efforts of various organizational subunits	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Establishing a uniform basis for prioritizing projects	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Achieving a general level of agreement regarding the risks/tradeoffs among system projects	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Avoiding the overlapping development of major systems	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
Capabilities	Ability to identify key problem areas	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Ability to anticipate surprises and crises	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Flexibility to adapt to unanticipated changes	(Newkirk & Lederer, 2006, Newkirk et al., 2003)
	Ability to gain cooperation among user groups for IS plans	(Newkirk & Lederer, 2006, Newkirk et al., 2003)

The current financial crisis has negatively impacted plenty of activities and most of the family businesses have already found themselves in a new turbulent financial environment where uncertainty dominates and the market characteristics radically changes. Except for financial barriers, their lack of technological, managerial and human capabilities may restrict their ability to bowl over the financial crisis (Bourletidis et al., 2014). Also, the lack of strategic planning negatively increases this difficulty. It appears that formal processes in SMEs which are connected with strategic management and information handling support managers to pay attention to strategies, structures and processes that are expected to increase firm performance. In uncertain environments, businesses should formalize processes using standardized rules and procedures which support the lowering of environmental uncertainty and arrange economic consistency. Formalization encourages the development of frameworks that request communication among the individuals as well as sharing of new information, and also supports the transformation of new ideas into real plans through the flexible structures. The result is the raise of innovation (Giannacourou et al., 2015).

SISP is a formal process which can be followed by SMEs in order to determine IS strategy and develop the most suitable IS for their needs. This process supports businesses to make decisions on the planning and the development of IS, analyzing their resources taking not only the environmental opportunities but also the threats into consideration. Also, SISP includes all the factors and the activities which are presented above as the advantages of the formalization. In this view, Mirchandani & Lederer, (2014), investigated SISP phases and they found that as the environment becomes more uncertain, more situational analysis is needed. The analysis of current business systems, organizational systems and IS, as well as current external and internal business environment and the current external IT environment allow the organization to identify problems and diagnose opportunities.

The findings of these surveys show that IS executives went their efforts into the strategic conception phase. Despite the fact that planners put their efforts into this phase, they cannot define the suitable alternative strategies so their efforts do not affect SISP success. As a result, they cannot achieve their aims. The most common problems which have been observed during the SISP process are the lack of participation and the failure to implement strategic IS plans. Executives cannot be committed to the plan, so the team has difficulties to implement the IS strategy. Also, findings highlight that executives understand that the implementation phase is difficult but very important and they are looking for ways in order to pay more attention on this phase (Lederer & Sethi, 1991, Newkirk & Lederer, 2006, Newkirk et al., 2003, Zubovic, et al., 2014). Internet can be used as a tool which supports the communication between the individuals and increases their participation to the process (Andersen, 2001). Except from Internet all the IT applications can support the knowledge sharing and the communication between the individuals (Pai, 2006). The participation between the members of the team is increased when CEOs support the process (Brown, 2010, King & Teo, 2000).

Results show that several managers put too much efforts to SISP process while others too little. In the first case, the process could be confused, detained or its implementation is prevented. In the second case, the implemented plans could be inefficient and they could not meet the objectives. So, the evaluation of the process is very important because managers can avoid these unsatisfactory results.

Findings conclude that managers focus on Strategy Conception and Strategy Implementation and they do not concentrate on Strategic Awareness and Situation Analysis, so the implemented plans are not effective, successful and they do not meet the aims (Brown, 2010, Newkirk & Lederer, 2006, Newkirk et al., 2003). Also, the strong focus on the implementation of the process leads to shorter SISP horizons but the strategic objectives have

not been achieved. Executives do not concentrate on what strategic aims really matter and how they can add value to the business because they pay attention to the horizon of the project and to reduce its cost due to limited IT budget (Brown, 2010). The results suggest that planners should pay attention on conducting situational analysis with greater punctiliousness, so they can develop strategy conception and strategy implementation planning with greater versatility than they currently implement. Managers should analyze their current business systems, organizational systems, IS, business environment and external IT environment. An understanding of those elements can improve the outcome of the planning process despite the fact that the time and cost will be increased. When managers understand the environment, they can identify significant IT objectives and opportunities for improvement, evaluate them for improvement and identify high level IT strategies in their business' strategy conception (Mirchandani & Lederer, 2014 Zubovic, et al., 2014).

FUTURE RESEARCH DIRECTIONS

This study has focused on the implementation of a digital strategy through SISP process. As a result, further empirical research is required to determine the success of SISP, especially in SMEs. More research could also be realised in the effect of factors (such as management commitment, horizon of projects, clear strategic objectives, financial support) in the success of SISP. So, the results of an exploratory study will be summarised in a conceptual model for further research. Finally, researchers can use different dimensions in order to measure SISP success and they can use tools from strategic management in order to implement each phase more effectively and to develop a successful digital strategy. In this view, they could examine if the methodologies used in the formulation, implementation and evaluation of

business strategy can be implemented in each phase in order to be developed a digital strategy.

CONCLUSION

Up to now academic studies have not focused on the impact of SISP phases on success. This chapter presented a framework which can provide a formal process to be followed by IS executives and managers in order to plan and use the right IS and to raise competitive advantage.

The authors contribute to the existing studies by increasing IS executives awareness of the strategic use of IS planning in order to accomplish success and competitive advantage. The presented framework is significant for SMEs. SMEs are very important for national and global economy but they do not implement strategic planning, so they cannot increase their resources as well as their competitive advantage. SMEs should develop strategic planning in order to develop and use IS according to their resources and their needs.

KEY TERMS AND DEFINITIONS

Alignment: The connection between business strategy and IS strategy.

Firm Performance: The power of a business to implement activities better rather than its competitors.

Resources: Resources can be categorized into physical, organizational, technological and financial. They are unique, they give value to the business and they cannot be copied by competitors.

Strategic Awareness: This phase includes the identification of key planning issues, planning objectives, organizing the planning team and the encouragement of top level managers.

Strategic Analysis: This phase involves analysis of current business systems, current organizational systems and current IS. Also, it includes the analysis of the current external and internal business environment and the current external IT environment.

Strategy Conception: This phase contains the determination of main IS objectives, opportunities for improvement, alternative scenarios as well as the evaluation of opportunities for improvement.

Also, it includes the definition of high level IS strategies.

Strategy Formulation: In this phase, businesses select the most suitable scenario from the previous alternatives scenarios, according to new business processes and new IT architectures. Then this scenario is evaluated according to its strategic and technological impact. Also, in this phase, specific new projects and priorities for new projects are identified. These projects consist of specific activities which support the implementation of the selected scenario.

Strategy Implementation Planning: This phase involves an approach and the actions of change management and the evaluation of strategic plan.

Strategic Information Systems Planning: The process of finding opportunities through IT which will add value to the organization, aligning its goals with IT and increases competitive advantage.

Sustainable Advantages of Business Value of Information Technology

B

Jorge A. Romero

Towson University, USA

INTRODUCTION

The business value of information technology (IT) and the way to sustain returns obtained through investment in IT has been a topic of interest in the last few years. Early studies during the 1980s and early 1990s on the relationship between business value and information technology investments did not find a link between them, although the firms analyzed at that time were investing large amounts of money on IT. This issue created what is called in the literature “the IT productivity paradox” (Brynjolfsson, 1993). It is essential to understand the relationship of IT and its effects on business value, especially the sustainable advantages that companies can obtain if they use IT to obtain a strategic differentiation and operating efficiency in using competitors as a benchmark.

Later studies have criticized the business value of IT investments claiming that IT does not bring any benefits to a firm because competitors can also have access to the same type of IT, thus eliminating any strategic advantage that a firm may have when they adopt a new type of IT (Carr, 2004).

However, more recent studies have found that IT improves productivity and profitability (Brynjolfsson and Hitt, 1996; Romero et al., 2010), and that IT can help firms differentiate their products from competitors and manage processes in a more efficient way (Anderson et al., 2011). For instance, Bardhan et al. (2013) proposed that IT investments interact with research and development investments of a firm enhancing its market value, and the results are visible through the increase in shareholder value. They used investments in research and development which is an intangible

variable that can be used as a proxy measure of the value and capabilities of a firm. They concluded that IT investments create business value, and they measured it with Tobin’s Q, which is a financial measure that takes into consideration future earnings and future growth of the firm.

With regard to the methodology used in most of the studies on the effects of business value of IT, most were based on cross sectional studies using data across industries and across different types of IT such as Enterprise Resource Planning (ERP), Customer Relationship Management (CRM), Material Requirements Planning (MRP), Supply Chain Management (SCM), and cloud-based applications among others. One criticism of this methodology is that each type of IT differs from another, including different installation periods and different investments, therefore the conclusions reached in these studies need to be analyzed with this in mind. Very few studies have looked at the business value of information technology using only one industry and using only one type of IT.

BACKGROUND: INDUSTRY STUDIES

Previous studies have concluded that the implementation of IT and its effects may affect firms in different industries in different ways (Porter, 2001; Melville et al., 2004; Mitra, 2007). Therefore, it is important to recognize the structural differences across industries when we try to measure business value and the managerial ability of firms applying IT in order to improve their performance. The understanding of those structural differences is not yet completely understood (Melville et al. 2004).

From a methodological point of view, it is possible to control industry effects in a regression across industries, but the concern with those studies across industries is that the industry effect may be averaged out when analyzing firms from a broad group of industries. On the contrary, in a study that focuses on one industry, the effect of industry-related factors are controlled and the unique characteristics of the specific industry can be taken into consideration in order to isolate the IT effects (Mitra, 2007). There have been very few industry studies analyzing the effect of business value of IT. The main limitation has been the difficulty to obtain and collect this kind of data which is more precise and accurate than cross sectional data. One of the advantages of an industry study is that it does not restrict the analysis; rather it minimizes the possibility of bogus results due to structural differences among industries.

For instance, Anderson et al. (2011) is one of the few industry studies that analyzed the effects of one type of IT within one specific industry. Using only one industry gave them the opportunity to avoid interactions among industries, to have a more homogenous dataset and to use this industry as a control variable. Using highly specific industry data, their study used a novel model to look at the business value that is generated during the implementation and after the implementation of one type of IT. They also looked at whether or not the business value of IT was sustainable over time. They concluded that firms that were involved in shorter IT implementations outperformed firms that were involved in longer IT implementations. One of their explanations for these results is that when a firm is involved in a long implementation, then structural changes within the firm and macroeconomic changes that may occur during the implementation may affect the implementation, whereas during a short implementation, firms avoid this potential issue. Also, during a long implementation, firms also face the possibility of having an outdated system by the time the implementation is complete. They also discussed that firms involved in shorter IT implementations

started to enjoy operational improvements before the IT implementation was officially declared complete. This is even more critical on large IT systems such as ERP where the operations of the whole firm may be affected and its supply chain interactions may also be affected.

BUSINESS VALUE ON ENTERPRISE RESOURCE PLANNING

It is important to discuss ERP as one type of IT because it is one of the most important types of IT that have had an important effect on business value of firms in the last two decades. ERP is a type of IT that is capable of processing enormous amounts of data and has become a widely-used package, particularly after major events such as the year 2000 problem (Y2K) when firms had to start using four digits in the variable year starting on year 2000. This, combined with the enforcement of the Sarbanes-Oxley Act of 2002 that imposed stringent accounting regulations on firms after several major financial scandals that included large publicly traded firms such as Enron, Adelphia, and Worldcom, among others, led to an increase in the use of ERP. With the enforcement of the Sarbanes-Oxley Act of 2002, ERP has helped firms standardize business processes and helped firms integrate their systems with the systems of suppliers and customers.

ERP has been considered as an extension of MRP II, but with more sophisticated features and applications (Gumaer, 1996; Yusuf and Little, 1998). Likewise, MRP was designed to replace legacy reorder point-based IT systems in production and planning departments (Cooper and Zmud, 1990). Large and complex IT systems such as ERP, that are very expensive and take a long period of time to implement, may generate disruption in the operations and will affect profitability of a company (Bardhan et al. (2013).

There are multiple studies on ERP, but there are few studies analyzing the effect of business value of IT over long periods of time using only

one type of IT such as ERP. Previous studies have not found any issues or any vendor related effects using only one type of IT. In the case of ERP, not every vendor may offer an identical package and similar functionalities in their ERP systems and prices and support offered by the corresponding vendor may be different. In addition, the complexity of each ERP system may be different, therefore more complex systems may impact firms in different ways (Reck, 2004).

Hunton et al. (2003) analyzed the effects of ERP comparing ERP-adopters versus non-adopters. They also identified the different ERP vendors associated with each data point in their sample and run a statistical test to see if there was a vendor effect that may affect the results based on the fact that not every vendor offers an identical system and there is a difference in price and support provided by each vendor. They concluded that there was no statistically significant vendor effect.

Most of the previous studies on ERP did not use detailed implementation data, go live dates, or types of ERP modules installed providing limitation on the types of conclusions that can be generalized (e.g. Hitt et al., 2002; Hunton et al., 2003; Nicolau, 2004; Nicolau et al., 2006). Reck (2004) concluded that, based on the results from previous studies, there were still contradictory results on the effects of IT on business value. Later on, Stratman (2007) concluded that the adoption of ERP by firms did not guarantee them a sustainable advantage over competitors or a positive return on investment.

Romero et al., (2010) is one of the few studies that used a specific industry to analyze the effects of business value on one type of IT: ERP. The analysis covered an important period of time during which firms were making large investments in ERP, and the dataset that they used had detailed information about installation periods and helped them isolate the effects of ERP. They looked at profitability ratio and its five components: profitability ratio, productivity ratio, capacity utilization ratio, product mix ratio, and price recovery ratio in order to drill down on the sources of profitability.

Their model used the pre-implementation period as a benchmark and the group of non-adopters as a control group. They concluded that the source of profitability was coming from the following two components: productivity and capacity utilization. Another important contribution of this study to the literature on business value is that the model used in this study can be easily applied to other types of IT.

FUTURE RESEARCH DIRECTIONS: CLOUD COMPUTING

New types of IT, such as cloud computing, will have a great impact on business value and firms will have to adapt their business models in order to incorporate this new IT. Cloud computing is a general term that can include ERP services, CRM services, online storage, or backup services. The growth rate of cloud services has grown at a higher rate than the ones of IT services in general (Choudhary and Vithayathil 2013). Cloud-based ERP applications are also available (Choudhary and Vithayathil 2013).

Cloud computing allows firms to reduce costs and can be deployed in a short period of time. Firms can reduce cost because the cost structure is based on the number of users and the period of time that the software will be used. For instance, the period could be a month, a quarter or a year (Chatman, 2010). Firms that use cloud-computing services eliminate fixed IT costs, and only incur variable costs based on their usage (Choudhary and Vithayathil 2013). Cloud software is also scalable so it can support an increase in the number of users, if needed (Chatman, 2010). When we talk about cloud computing, we are not only looking at the services offered but also at the rental of computing and storage (Choudhary and Vithayathil 2013).

Choudhary and Vithayathil (2013) looked at cloud computing as a service to the firm. They also noted that cloud computing services are standardized products with a limited amount of customization. Cloud computing services are

expected to offer high quality services; otherwise it will be very difficult and costly for the firm to try to improve the quality of the vendor.

With regard to business value and competitive advantage that firms may get in relation to competitors, firms that use cloud computing applications have to accept that cloud computing services are standard for all firms using that service, a characteristic that may affect the business value of the firm in relation to competitors (Choudhary and Vithayathil 2013).

Cloud computing gives firms the possibility of getting real-time data, anywhere connectivity, as well as affordable digital optimization to generate business value and competitive advantage by creating customer intimacy through the use of algorithms designed specifically to identify each customer, and by creating operational excellence based on a more agile process (Weinman, 2015).

Cloud computing can foster business innovation and can create business value because business units in a firm do not need to depend on their corresponding IT department for technology needs, business department can bypass their IT departments and rent what they need from the cloud and pay as-they-go. In the past, IT department were not always synchronized with the needs of the business units, because sometimes IT departments had limited budgets, and limited personnel that not let them satisfy the business needs of the different departments and did not let them provide the IT infrastructure in a timely manner (Andriole, 2015). More research needs to be done in this area of cloud computing in order to examine the effects on business value.

CONCLUSION

Recent studies on the business value of IT using detailed data on one specific industry and using only type of IT have shown that IT provides a competitive advantage over competitor. The way to sustain the advantage is to see the investment in IT as a life cycle investment because technology

changes at a rapid pace, so firms have to be continuously innovating in order to keep their competitive advantage. One way to do it is to always stay at the forefront of technological innovations. For example, cloud computing is changing the way that firms do business and the way firms handle electronic records.

The proposal of Clemons and Row (1991) still holds on the fact that the strategic advantage will be sustainable only if the firm uses the IT in such a way that competitors cannot replicate the system. Competitors can buy the same type of IT, it may be the same type of ERP or they may be renting the same type of cloud service, and may try to replicate the system, but the only way to keep a strategic advantage over competitors is to see investments in IT as a life cycle investment in which the firm is constantly seeking ways to differentiate itself from competitors and to use its unique characteristics and unique resources to combine with IT to sustain the advantage over competitors, and therefore increase the business value of the firm. One way to differentiate from competitors and gain a sustainable competitive advantage is to add value and unique characteristics to the standard services provided by cloud computing services that can also be used by competitors.

This chapter provides a blueprint to conduct more research on this dynamic topic and will help researchers and managers to gain knowledge on the impact of IT. This chapter will also help researchers, managers and senior executives to identify the sources of competitive advantage and their managerial and strategic value to investments in IT.

KEY TERMS AND DEFINITIONS

Business Value: It is the value of a firm that not only includes the monetary value of a firm, the hardware, the software, and the IT organizational processes but also includes other intangible components such as innovation, integration, standardization of processes, efficiency, and quality of products produced.

Cloud-Based Applications: Applications that do not need to be installed or run from a desktop or server on premise in a firm (Choudhary and Vithayathil, 2013). They are applications that are hosted on remote servers and that can be accessed via the Internet from anywhere. It offers an advantage to firms avoiding the acquisition of IT assets that usually depreciate at a fast rate. Because the software is not installed on site, firms do not need to invest on upgrading software regularly or to pay annual license fees. However, there is a pay as-you-go fee in cloud applications (Choudhary and Vithayathil, 2013).

Customer Relationship Management: Also known as CRM. CRM with the use of technology supports a firm managing its interactions with customers and focuses on customer retention with the purpose of maximizing profitability (Weinman, 2015). It is mostly considered a business and strategic solution rather than a software solution. CRM integrates different parts of a company that deal with customers such as: sales, advertising, direct mail, email, and call centers in order to improve customer communication and to increase competitiveness. With the use of CRM is possible to identify customer preferences. There have been case studies of companies failing to extract benefits from CRM installations mostly due a poor understanding of the system and not an adequate training of employees using the system (Chen and Popovich, 2003). For instance, Salesforce, headquartered in San Francisco, is a cloud-based CRM package and is currently one of the market leaders that includes the following components: marketing cloud, analytics cloud, sales cloud, and service cloud.

Enterprise Resource Planning: Also known as ERP and was developed in the 1990's. An ERP system attempts not only to integrate all departments within a company but also to synchronize the ERP system of the firm with the ERP systems of others companies in the supply chain that it operates (Anderson et al., 2011). An ERP system consists of several modules such as finance, sales, human resources, inventory, operations, and marketing among others. An ERP system is deemed complete when all modules are installed, and it is preferably to install all modules from the same vendor in order to avoid any compatibility issues (Romero et al., 2010). Having all departments synchronized let a company know the status of an

order at any point in time, and if there are changes in an order, all systems are updated automatically without having a need to update the systems of each department one by one.

Information Technology: Information technology includes the use of computer software, computer hardware, telecommunications equipment and services. It provides support to firms to store data, process data, synchronize and monitor processes. It also allows managers to think at a more strategic level because they do not need to spend time or resources on repetitive or administrative tasks that are being performed by the information technology (Romero et al., 2010).

Material Requirements Planning II: Also known as MRP II and was developed in 1980's. MRP II evolved from MRP incorporating some additional features such as the master production schedule using the available-to-promise logic, sales forecasting,, and tracking tools until the items are delivered to customers among other tools (Olhager, 2013).

Material Requirements Planning: Also known as MRP. MRP was developed in the 1960's and 1970's as a production planning system to support manufacturing operations calculating the amount of raw materials needed by the production department and the specific timing of different individual parts that are needed (Jodlbauer, 2012). MRP also helps managers decide when to buy.

Supply Chain Management: Also known as SCM. SCM is a group of different firms that work in a coordinated way and are linked together to maximize competitive advantage. It is composed of suppliers of raw materials, firms that process those raw materials, and retailers that sell the products to the final customers.

Using Business Analytics in Franchise Organizations

Ye-Sho Chen

Louisiana State University, USA

INTRODUCTION

Franchising has been a popular approach to growing a business (Justis & Judd, 2002). Its popularity continues to increase, as we witness an emergence of a new business model, Netchising, which is the combination of the Internet for global demand-and-supply processes and the international *franchising* arrangement for local responsiveness (Chen, Justis, & Yang, 2004; Chen, Chen, & Wu, 2005, 2007; Chen & Wu, 2007; Chen, Liu, Zeng, & Azevedo, 2012).

BACKGROUND

In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote: "Information Technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other." (p. 6) Gates' point is quite true when one talks about franchise's use of big data and business analytics, which is "delivering the right decision support to the right people at the right time" (Laursen & Thorlund, 2010, p. xii). Thus, to see how big data and business analytics can be "meaningfully" used in franchise organizations, one needs to know how franchising really works. In this paper, we show that building up a good "family" relationship between the franchisor and the franchisee is the real essence of franchising, and proven working knowledge is the foundation of the "family" relationship. Specifically, we use the following seven pillars of business analytics (Isson & Harriott, 2013) to discuss the process

of how to make business analytics "meaningful" in franchising: business challenges, data foundation, analytics implementation, insights, execution and measurements, distributed knowledge, and innovation.

BUSINESS CHALLENGES: MANAGING THE FRANCHISOR AND FRANCHISEE RELATIONSHIP

Franchising is "a business opportunity by which the owner ... grants exclusive rights to an individual for the local distribution... The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate ... is called the *franchisee*." (Justis & Judd, 2002, pp. 1-3) Developing a good "family" relationship between the franchisor and the franchisee is the key business challenge of a successful franchise (Justis & Judd, 2002). Figure 1 describes how such a "family" relationship is built in the franchise business community. In the figure, it shows that the franchise system is operated in the dynamic business environment of global, national, regional, and local communities. The "family" relationship is developed through a mutual learning process of person-centric relationship building.

The franchisor's learning process is incrementally developed through five stages (Justis & Judd, 2002): Beginner – learning how to do it; Novice – practicing doing it; Advanced – doing it; Master – teaching others to do it; and Professional – becoming the best that you can be. Once attaining the advanced stages of development,

Figure 1. Understanding how the franchisor/franchisee “family” relationship works

most preceding struggles have been overcome. However, further convoluted and challenging enquiries will arise as the franchise continues expansion. This is especially true once the system reaches the “Professional” stage, where various unpredicted and intricate problems could arise. To capture the learning process, a counter-clockwise round arrow surrounding the franchisor is used to depict the increasing intensity of learning as the franchisor continues to grow.

To understand how the “family” relationship is developed, one needs to know the five phases of franchisee life cycle (Schreuder, Krige, & Parker, 2000): Courting: both the franchisee and the franchisor are eager with the relationship; “We”: the relationship starts to deteriorate, but the franchisee still values the relationship; “Me”: the franchisee starts to question the reasons for payments related issues with the attitude that the success so far is purely of his/her own work; Rebel: the franchisee starts to challenge the restrictions being placed upon; and Renewal: the franchisee realizes the “win-win” solution is to continue teaming up with the franchisor to grow the system. Similar to the franchisor, a counter-clockwise round arrow surrounding the franchisee is used in Figure 1 to depict the increasing intensity of franchisee life cycle as the franchisee continues learning and growing.

As the franchisee progresses through the life cycle, the “family” relationship gradually develops a mutually influencing process (Justis & Vincent, 2001) as depicted in Figure 1 with a bi-directional arrow: working knowledge, proven abilities of expanding the franchise system profitably; positive attitude, constructive ways of presenting and sharing the working knowledge; good motivation, providing incentives for learning or teaching the working knowledge; positive individual behavior, understanding and leveraging the strengths of the participants to learn and enhance the working knowledge; and collaborative group behavior, having the team spirit to find the best way to collect, disseminate, and manage the hard-earned working knowledge. By going through the processes of learning and influencing, both the franchisor and the franchisee gain the progressive working knowledge in the franchise business community. The franchisor, the franchisee, and the franchise business community in Figure 1 are surrounded with dashed lines, indicating that there is no limit to the learning process.

DATA FOUNDATION: MANGING FRANCHISE BIG DATA

There are many “touchpoints” within the franchise business community where the franchisor and

Table 1. The customer-service-life-cycle model in franchising

Requirements	Understanding How Franchising Works	Internet • WSI Proven Franchise Business Model • WSI Franchise Lifecycle • Master Franchise Opportunities
	Investigating Franchise Opportunities	Internet • About WSI • Client Portfolio
	Obtaining Franchisee Prospectus	Internet • E-mails
	Making the Choice	Internet • Global Franchise Leader • Success Stories • WSI in the News
Acquisition	Preparing Business Plan	Internet
	Financing the Franchised Business	Internet
	Signing the Contract	Internet • Own a WSI Franchise
Ownership	Marketing & Promoting the Franchise Products or Services	Internet/Intranet/Extranet • WSI Proven System
	Managing the Franchise System	Internet • WSI Community Outreach Intranet • Franchise Training and Support • Serving Franchisee's Customers Extranet
	Building the Relationship between the Franchisor and the Franchisee • The Courting Phase • The "We" Phase • The "Me" Phase • The Rebel Phase • The Renewal Phase	Internet Intranet • Knowledge Centre • Training at Headquarters • Newsletter • Meetings • Toll-free Phone Line Extranet • Purchasing Cooperative
Renewal or Retirement	Becoming a Professional Multi-unit Franchisee or Retiring from the Franchise System	More refined and diverse views of the customer information are gathered through Internet, Intranet, and Extranet at the different stages of "touchpoints". This will help the franchise system look into the customer insights (Suther, Burkart, & Cheng, 2013) and better serve the customers.

the franchisee can influence each other. Based on the Customer Service Life Cycle (CSLC) model, Chen, Chong, & Justis (2002) proposed a framework (Table 1) to harness the Internet to develop the big data foundation needed to serve its customers, i.e., franchisees and their customers. Three exemplar types of data are (1) unit operational data: the daily activities at the franchisor headquarters; (2) external benchmarking data: the relationship management activities in the

franchise community; and (3) business legacy data: the activities that have been working well or gradually adapted since the franchise system came into existence.

To tap the full potential of the CSLC framework, more refined and diverse views of the customer information shall be gathered at the different stages of "touchpoints". This will help the franchise system look into the customer insights (Suther, Burkart, & Cheng, 2013) and better serve

the customers. A well-designed Internet strategy, often enabled by Application Service Providers (Chen, Ford, Justis, & Chong, 2001), shall empower the franchisor and the franchisees to collect, use, renew, store, retrieve, transmit, and share the organizational data needed to do the collaborative work in the various phases of the CSLC model.

ANALYTICS IMPLEMENTATION: MANAGING FRANCHISE ORGANIZATIONAL INFORMATION

An architecture, adapted from Inmon (1996) and Thomas & McSharry (2015), of big data and business analytics in franchising is shown in Figure 2. The architecture consists of four levels of operational processes: (1) data collection level, holding operational, external, and legacy data collected from the franchise business environment depicted in Figure 1; (2) reconciled data level, holding data warehouse data and meta data; (3) derived data level, containing several data marts derived from the data warehouse based on various franchisee/customer-centered segmentations; and (4) the analytical presentation level, producing various relationship performance indicators with strong data visualization capabilities for decision making via decision support systems (DSS). To move from the data collection level to the reconciled data level, data integration is needed. It is a very time consuming process that involves the activities such as recovery, cleansing, extracting, filtering, conditioning, scrubbing, and loading. To move from the reconciled data level to the derived data level, data transformation is needed which involves the activities such as exploration, replication, propagation, summary, aggregate, and metadata. To move from the derived data level to the analytical presentation level, data analysis is needed which involves activities such as online analytical processing (OLAP) and data mining (Chen, Zhang, & Justis, 2005; Chen, Justis, & Chong, 2008).

A typical OLAP analysis consists of pre-defined multi-dimensional queries such as (Chen, Justis, & Watson, 2000): (1) Show the gross margin by product category and by franchise outlets from Thanksgiving to Christmas in the last five years; (2) Which franchise outlets are increasing in sales and which are decreasing? And (3) Which kinds of customers place the same orders on a regular basis at certain franchise outlets? Other OLAP activities include spread sheet analysis, data visualization, and a variety of statistical data modelling methods. Since the query activities are pre-defined, we call the supporting systems reactive DSS.

Data mining is used to identify context-sensitive patterns of the data residing in the data marts. Typical data mining modelling analysis can be classified into the following three categories: Classification and Prediction, using techniques such as RFM (recency, frequency, and monetary), regression, decision tree, and neural network; Association Rules, using techniques such as market basket analysis, correlation analysis, cross-sell analysis, and link analysis; and Cluster Analysis, using techniques such as partition, hierarchy, outlier, and density analysis. Table 2, adapted from Delmater & Hancock (2001), shows that data mining techniques can be used to help serve franchisees' customers at the different stages of the CSLC model.

Since the data mining queries and related activities are not pre-defined, we call the supporting systems proactive DSS. A major drawback of proactive data mining is the fact that without vigilant preliminary examination of data characteristics, the mining activities may end in vain (Delmater & Hancock, 2001). In order to achieve higher success rate of data mining, we suggest (on the right side of Figure 2) that OLAP-based queries need to be conducted first. For example, one may find, through daily OLAP queries, that certain segments of customers buy certain products frequently. This pattern may lead to perform thorough and proactive analysis of the customer-product relationship and human resource analytics (Pease, Byerly, & Fitz-enz, 2012). The results may

Figure 2. Architecture of big data and business analytics in franchising

help the company provide legendary services to its clients and generate higher profits.

INSIGHTS: MANAGING FRANCHISE ORGANIZATIONAL WORKING KNOWLEDGE

As mentioned in the discussions of Figure 1, the key for building the franchisor/franchisee “family” relationship is in the franchise organizational learning. In addition, there are five vital insights for a successful learning program: knowledge, attitude, motivation, individual behavior, and

group behavior. Thus, working knowledge is the real foundation of a successful franchise “family” relationship. The working knowledge is structured in many forms of profiles that are embedded in the operational manuals of the franchise business processes. Table 3 gives some examples of those working knowledge profiles with respect to the CSLC business processes associated with the sub-stages in Table 1.

A working knowledge profile is developed when a certain task of the CSLC process is repeated several times with superior results. Consider the Site Profile used at the “Marketing & Promoting the Franchise Products/Services” sub-stage in

Table 2. Franchisees' customers data mining using the CSLC approach

CSLC	Explanation	Data Mining (and Techniques Used) for Context-Sensitive Patterns
Requirements	Finding and reaching the customers	Context-Sensitive Lead Generation • Market Analysis & Segmentation (Classification and Prediction) • Mining Web Site Visitors (Association Rules) • Text Mining Usenet Newsgroups (Cluster Analysis)
Acquisition	Selling to the customers	Context-Sensitive Customer Acquisition Profiling • Customer Segmentation Strategy (Classification and Prediction) • Online Shopping Tracking (Association Rules) • Pricing Strategy (Association Rules) • Customer-centric Selling (Association Rules) • Text Mining Contact E-Mails (Cluster Analysis) • Scenario Notification (Association Rules)
Ownership	Satisfying the customers after the sales	Context-Sensitive Customer Service • Inquiry Routing (Association Rules) • Text Mining E-Mails & Inquiries (Cluster Analysis) • Scenario Notification (Association Rules) • Staffing Level Prediction (Classification and Prediction)
Retirement or Renewing	Retaining the customers so that you can continue coming back	Context-Sensitive Customer Retention • Sharper Customer Focus through Loyalty Program (Classification and Prediction) • Detecting Customer Complaints through Text Mining (Cluster Analysis) • Detecting Inappropriate Customer Services (Cluster Analysis) • Individual Customer Profiles (Classification and Prediction) • Scenario Notification (Association Rules)

Table 3. The Site Profile is used to assist the new franchisee locate a top business site. Typically it is the real estate department at the franchisor headquarters responsible for the profile development. The Site Profile is unremittingly being tested and enhanced. Various OLAP/Data Mining analytical reports, monitoring the performance of the sites, are generated at the Analytical Presentation Level shown in Figure 2. Based on those reports, the real estate experts and their teams are able to fine-tune the attributes and the parameters within the Site Profile. Most often, the corresponding data collection procedures in the CSLC sub-stage also need to be revised and perfected so that better scorecards can be generated.

EXECUTION AND MEASUREMENTS: DEVELOPING A GROWING FRANCHISE

This process of executing and enhancing the working knowledge profiles will achieve its high peak when both the franchisor and the franchisees are

Table 3. The CSLC model of franchise working knowledge

CSLC Sub-stages	Examples of Working Knowledge Profiles
Understanding How Franchising Works	Lead Generation Profiles Website Visitor Profile
Investigating Franchise Opportunities	Benchmarking Profile Successful Franchisee Profile
Obtaining Franchisee Prospectus	Prospectus Profile
Making the Choice	Competitor Profile
Preparing Business Plan	Business Plan Profile
Financing the Franchised Business	Financing Institute Profile Non-traditional Franchising Profile
Signing the Contract	Franchisee Profile
Marketing & Promoting the Franchise Products or Services	Site Profile Product Profile
Managing the Franchise System	Support Team Profile Employee Profile Demand-Supply Matching Profile
Building the Relationship between the Franchisor and the Franchisee	Event Management Profile Best Practices Profile
Becoming a Professional Multi-unit Franchisee or Retiring from the Franchise System	Multi-unit Franchisee Profile Social Networks Profile

arriving at the Professional and Renewal stage of growth. A significant phenomenon of being a Professional franchisor and a Renewal franchisee are their ability to leverage the assets of the hard-earned working knowledge profiles into dynamic capabilities and high-business-value-creation complete-advantage strategies (Chen, Yuan, & Dai, 2004; Chen, Seidman, & Justis, 2005). Business performance tracking, using mobile analytics (Munteanu & Puican, 2012) with effective analytics communication strategies, is very important here. The new products or services coming out of the process of leveraging the working knowledge profiles may transform the franchise business into a more, sometimes surprisingly, profitable enterprise.

The capability of leveraging the assets of franchise working knowledge into profitable products or services is at the heart of a successful franchise. For instance, consider the site selection working knowledge at McDonald's. The Franchise Realty Corporation real estate business, a result of site selection asset leveraging, is the real moneymaking engine at McDonald's. This as can be evidenced from the following speech of Ray Kroc, founder of McDonald's, to the MBA class at the University of Texas at Austin in 1974: "... I 'm not in the hamburger business. My business is real estate." (Kiyosaki, 2000, p.85) In the book *McDonald's: Behind the Arches* (Love, 1995, p. 152), Ray Kroc commented further: "What converted McDonald's into a money machine had nothing to do with ... the popularity of McDonald's hamburgers, French fries, and milk shakes. Rather, McDonald's made its money on real estate" McDonald's makes money out of real estate by leasing properties from landlords and then subleasing the stores to the franchisees. The Professional franchisees, many of them are multiunit operators, can then focus on expanding the business without worrying about finding good locations for the growth. This moneymaking real estate strategy is what separates McDonald's from other fast-food chains.

DISTRIBUTED KNOWLEDGE: FRANCHISE KNOWLEDGE REPOSITORY

Knowledge repository systems, consisting of working knowledge profiles such as the one shown in Table 4 (Chen, Chong, & Justis, 2000; Chen, Hammerstein, & Justis, 2002; Chen, Justis, & Wu, 2008), can be linked into the franchisor headquarters and the franchisee outlets for knowledge sharing and learning. Such a repository has two dimensions. First, there is a working knowledge level for the collaborative team, the franchisee outlet, the franchisor headquarters, and the franchise community. Second, there are user skill levels, including Beginner in the Courting Phase, Novice in the "We"-Phase, Advanced in the "Me"-Phase, Master in the Rebel Phase (since the rebel ones tend to be those who know the system very well and are capable of influencing others to follow them), and Professional in the Renewal Stage of franchisee life cycle. The foundation of the framework is the working knowledge of the five crucial elements—Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior—used by the collaborative team, to effectively influence others in building the franchise "family" relationship. The working knowledge profiles at the franchisee outlet, the franchisor headquarters, and the franchise community can be modularized according to user's level. An Intranet-based curriculum of working knowledge modules can then be designed for the users to learn the working knowledge profiles effectively.

FUTURE RESEARCH DIRECTIONS: INNOVATION BY LEVERAGING FRANCHISE VALUE NETWORKS

The third industrial revolution, combining Internet technology with globalization, produces various new big data and business analytics opportunities

Table 4. Working knowledge repository in franchise organizations

		User Skill Levels				
		Beginner in the Courting Phase: Beginner Guide	Novice in the “We”-Phase: Practicing	Advanced in the “Me”-Phase: Doing	Master in the Rebel Phase: Teaching Others	Professional in the Renewal Stage: Improving and Leveraging
Working Knowledge Levels	Collaborative Team	Culture and Process of Influencing Others for Knowledge Sharing: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior				
	Franchisee Outlet	Learning and Training of Working Knowledge Profiles for Running the Franchisee Outlet: Customer Profile, Employee Profile, Product Profile				
	Franchisor Headquarters	Learning and Training of Working Knowledge Profiles for Running the Franchisor Headquarters: Franchisee Profile, Site Profile, Product Profile, Employee Profile, Event Management Profile				
	Franchise Community	Learning and Training of Working Knowledge Profiles for Relationship Management with the Community: Supplier Profiles, Community Profiles				

for the innovative growth of franchise organizations. For example, value network applications, using business analytics techniques such as social network analysis, can be developed to connect Professional franchisees in the world. The goal is to enable the franchise system to venture into new global emerging markets, e.g., China, through international franchising and develop innovative

products/services through asset leveraging. This could be done because franchise capabilities, structured in the working knowledge repository shown in Table 4, empower the Professional franchisees to work with the franchisor to continuously improve and leverage the current franchise working knowledge. An example of value networks of Professional franchisees can be illustrated in Figure 3.

Figure 3. Business analytics hub enhances and strengthens the value networks of professional franchisees

There are seven Professional franchisees (A - G) in the figure with four clusters (A-C, D, E-F, and G) of value networks. Each Professional franchisee (a dot) has his/her personal value network (arrows pointing out of the dot) tested and built over the years while doing day-to-day problems solving at the franchisee outlet. The value network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, the social needs in the local community. Each Professional franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal value network. In order to solve the problems more effectively, Professional franchisees may share with each other their approaches. Thus, clusters (connected dots) of value network are formed for solving various problems more effectively (Chen, Justis, & Wu, 2006). The big data gathered from the Professional franchisees and networks are connected to the business analytics hub to enhance and strengthen the value networks.

CONCLUSION

Franchising has been popular as a growth strategy for small businesses; it is even more so in today's global and e-commerce world (Chen, Chen, & Wu, 2005). The essence of franchising lies in managing the "family" relationship between the franchisor and the franchisee. In this paper we showed business analytics plays an important role in growing and nurturing such a "family" relationship. Specifically, we used the seven pillars of business analytics (Isson & Harriott, 2013) to discuss the process of how to make big data and business analytics "meaningful" in franchising: how franchise big data can be managed effectively using the methodology of Customer Service Life Cycle; how franchise organizational information is deciphered from the customer-centered data using business analytical techniques such as OLAP and data mining; and how the franchise

organizational working knowledge is leveraged to grow the franchise system. The ability to continue creating value networks by leveraging the organizational working knowledge assets based on the good "family" relationship is really what a franchise business is about.

KEY TERMS AND DEFINITIONS

Customer Service Life Cycle: Serving customers based on a process of four stages: Requirements, Acquisition, Ownership, and Retirement. Many companies are using the approach to harness the Internet to serve the customers.

Data Mart: A small database with data derived from a data warehouse.

Data Mining: Analytical techniques used to find out the hidden relationships or patterns residing in the organizational data.

Data Warehouse: A database which is subject-oriented, integrated, time-variant, and non-volatile.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, “We”, “Me”, Rebel, Renewal.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

INTRODUCTION

After developing the scholarly foundation of the existing disciplines, this paper will look specifically at how selected concepts relate across the fields, particularly to what we know about big data. Although not as developed a discipline, big data does have recognizable elements from its own and other literatures. This article will establish the links between fields and demonstrate opportunities for sharing and learning between the different disciplines, both old and new.

BACKGROUND

The field of knowledge management (KM) and its related discipline, intellectual capital (IC) have both contributed considerably to our understanding of the value of intangible assets of the firm. The general concept that intangibles are something worthwhile goes back at least to Schumpeter's (1934) work on innovation and has since included contributions from other high-profile writers such as Drucker, with his knowledge workers (1991). The idea that proper management of such intangibles might lead to competitive advantage was explored by scholars such as Nelson and Winter (1982) in their evolutionary theory of growth. Such competitive advantage fits well with the resource-based theory of the firm (Wernerfelt, 1984), specifically identifying knowledge as a potential key resource. As a result, we have the

knowledge-based theory of the firm (Teece, 1998; Grant, 1996) and its suggestion that knowledge is not only a potentially important differentiator but perhaps the only differentiator for firms looking for sustainable competitive advantage.

In pushing the field forward, the KM and IC disciplines have always carefully defined the nature of their study, perhaps because of the obvious need to clarify and distinguish knowledge assets or intellectual capital from the more widely known but explicitly formal intellectual property terminology. Patents, copyrights, and other intellectual property are valuable intangible assets, but intellectual capital extends our recognition of value to additional, less well-defined intangibles such as know-how and expertise (knowledge). As a result, a clear distinction exists in the field between data, information, and knowledge. Formally, data are observations, information is data in context, and knowledge is information subjected to experience, reflection, or some similar analysis (Zack, 1999b). Within the field, knowledge is often referred to as know-how, effectively a sort of learning based on experience, learning, or insight. Such a perspective flows naturally out of the more general DIKW (data, information, knowledge, wisdom) hierarchy suggested by Ackoff (1989).

Growth in knowledge of this sort can come about in different ways. Nonaka and Takeuchi (1995) borrowed the concept of tacit knowledge from the sociology literature (Polanyi, 1967), identifying and explaining tacit and explicit knowledge in a business context. Tacit knowledge

is more personal, harder to express, and more difficult to codify within organizational information technology (IT) systems. Explicit knowledge, on the other hand, is easier to express, easier to share, and easier to store in IT structures. Nonaka & Takeuchi also developed the SECI or ba framework categorizing how knowledge grows, by tacit to explicit, tacit to tacit, explicit to tacit, or explicit to explicit transfer. The explicit to tacit process is of particular interest as it concerns the conversion of more structured intangible assets into personal tacit insights. From there, it is only a short step to the idea of creating new knowledge from data and information, foreshadowing how non-knowledge intangible assets can also create value. The overall objective of KM is to better understand how knowledge can be more effectively developed and employed by means of combination, sharing, learning, or similar means (Zack, 1999a; Grant, 1996).

Since these early insights, knowledge management as a field has focused more on the circumstances surrounding knowledge development as well as appropriate tools. Beyond the tacit/explicit distinction, other circumstantial variables relating to knowledge development include other aspects of the knowledge itself as well as organizational conditions. Knowledge aspects include characteristics such as complexity and stickiness (McEvily & Chakravarthy, 2002; Zander & Kogut, 1995; Kogut & Zander, 1992). These essentially assess how complicated the knowledge might be (and difficult to fully understand) and how sticky or tied to the originating firm. Organizational aspects include characteristics like absorptive capacity (Cohen & Levinthal, 1990) and social capital (Nahapiet & Ghoshal, 1998). Absorptive capacity refers to the learning capabilities of the firm and its people while social capital refers to the number and strength of personal ties throughout the entity. As a consequence of the differing conditions, organizations pursue different KM approaches (Choi & Lee, 2003; Schulz & Jobe, 2001; Boisot, 1995) ranging from tacit-to-tacit techniques such as communities of practice or

storytelling to more explicit-oriented tools such as IT-driven knowledge markets (Matson, Patiath, & Shavers, 2003; Thomas, Kellogg, & Erickson, 2001; Brown & Duguid, 1991).

The related field of intellectual capital addresses many of the same basic concepts but from the standpoint of metrics, categorization, and strategic development of the assets. Growing out of scholar and practitioner interest in better accounting for fuzzy, intangible assets, IC typically looks to describe the knowledge assets of the firm according to the categories human capital, structural capital, and relational capital (Bontis, 1999; Edvinsson & Malone, 1997; Stewart, 1997). Human capital refers to individual, job-specific knowledge, structural capital to more long-term knowledge persisting in the organization (culture, systems), and relational capital to knowledge about relationships with those external to the firm.

A further extension adds in the idea of actionable intelligence. In many ways relatable to Ackoff's "wisdom" in the DIKW hierarchy mentioned earlier, intelligence refers to analysis of the knowledge (as well as the pre-knowledge data and information) in order to develop and execute strategies and tactics. Much like KM and IC, competitive intelligence grew out of practice as much as scholarship, especially early on (Prescott & Miller, 2001; Gilad & Herring, 1996; Fuld, 1994). Also similarly, the field often focuses on sources of knowledge, information, and data, as well as techniques for obtaining them (Fleisher & Bensoussan, 2002; McGonagle & Vella, 2002). Where matters start to diverge is in the analytic processes often applied to competitor knowledge and information, especially as competitive intelligence operations mature (Wright, Picton, & Callow, 2002; Raouch & Santi, 2001). Consequently, we do have some theory and practice related to the usefulness of all intangibles (data, information, and knowledge), not just knowledge, and the extension of creating actionable insights or intelligence, not just additional knowledge. Those fields looking for "intelligence" (competitive intelligence, marketing intelligence, business intelligence) have clear

connections with knowledge management but also have the potential to extend our understanding into new areas.

Within these interconnected structures and fields, scholars and practitioners have made substantial progress in identifying, understanding, and managing intangible assets. In recent years, data and information assets have reasserted themselves in the form of big data and business analytics. What can our understanding of knowledge assets and these related disciplines tell us about the potential value of the different approaches to big data?

Big Data and Knowledge

A number of factors have come together to create the new and exciting phenomenon known as big data, business analytics, business intelligence, or by any number of other names. The combination of ever increasing amounts of data generated by organizations, enhanced computing power, and the sharply decreased costs of storage and processing in the cloud have resulted in a greater interest in finding ways to benefit from better use of such data (Bussey, 2011; Vance, 2011b). Much of the data comes from operational systems (e.g. enterprise systems, supply chain management, supply chain/distribution channels) and/or transactional systems (e.g. customer relationship management, loyalty programs) (Vance, 2011a). Communication data, especially Internet-based or mobile (Google Analytics, social media) also has a role. While the databases are important to the process, it is the insights from analyzing the data that provide the strategic, tactical, and operational value. An oft-cited study from McKinsey Global Services notes the increased transparency available to big data practitioners allowing real-time experimentation, more precise segmentation, more objective decision-making via algorithm, and idea generation for new products (Manyika et al., 2011).

Although the scholarly literature related to big data is limited, it does have some history. Laney (2001) characterized the promise of data growth

as being wrapped up in volume of data, velocity of input and output, and variety of data, including sources. These three “v’s” have persisted over the past decade, including Laney’s (Beyer & Laney, 2012) own update that noted the volume, velocity, and variety allow new analysis techniques leading to deeper insights and better decisions.

Big data spans numerous industries and applications and is growing rapidly, especially in terms of explicit metrics like data storage (Liebowitz, 2013; Manyika et al., 2011). In constructing and utilizing an effective big data capability, however, organizations need some guidance, as just the hardware and systems are not sufficient. Decision-making can be enhanced by data systems, but the data systems also need a human element, the analytics, to be fully effective (Zhao, 2013). As noted above, the insights from the data are key. That requires intelligence, the ability to process, analyze, and make effective use of the data and information as well as marry the IT system to its human users.

This is where the intersection of the knowledge management, intellectual capital, and competitive intelligence frameworks can contribute. As hinted at in the literature review, some distinct connections between the fields have already been made. Big data treatments will sometimes acknowledge the KM and related literature in developing their conceptual foundation (Bose, 2009; Jourdan, Rainer, & Marshall, 2008). And intellectual capital, in particular has shown interest in expanding its purview, extending analysis to the full range of intangible assets (data, information, knowledge, intelligence) capable of providing value and competitive advantage to the organization. Andreou, Green, and Stankosky (2007), for example, constructed a framework including not just the traditional intellectual capital categories (or closely related ones) but also such items as competitive intelligence and enterprise intelligence, identifying all as potentially valuable corporate intangible assets.

Previous studies on the combination of KM/IC with competitive intelligence informs these links.

The structure and systems of KM differed from typical practice in competitive intelligence, often focusing on the IT and human interaction issues. Providing systems and incentives for employees to care about and make use of the KM structure was often the primary concern. Competitive intelligence, on the other hand, added ideas such as more targeted search, use of data and information as well as more developed knowledge, and the application of analysis with actionable results. Opportunities for cross-fertilization existed that could benefit the practice of both disciplines (Rothberg & Erickson, 2005). Recognition of both disciplines also made clear the security concerns when KM was fully leveraged, spreading organizational intangibles throughout extended networks (and thus more exposed to competitive intelligence efforts). Quantitative study demonstrated that both KM/IC and competitive intelligence practice faced dramatically different operating environments (Erickson & Rothberg, 2012). KM programs could be more or less effective in different industries while competitive intelligence could be a greater or lesser threat. Related depth interviews showed a similar wide variety in practice of both KM and competitive intelligence across industries and firms. Understanding the proper approach to KM/IC and competitive intelligence is strategic, with the right direction dependent on careful analysis of the firm, its industry, and other competitive circumstances.

One new direction in the field is found in revisiting the Ackoff DIKW hierarchy noted earlier. Kurtz & Snowden (2003) created the “Cynefin” sense-making framework, organizing intangible assets according to structure and distribution. As adapted by Simard (2014), this framework can be viewed as a hierarchy, running from data/information to explicit knowledge, then to tacit knowledge and on to insight/intuition. This form has a nature similar to DIKW but illustrates the similarities of the more structured, distributable assets such as big data (data/information) and

explicit knowledge while also highlighting their differences. Similarly, as tacit knowledge becomes even less structured and more personal, the distinctions are even clearer, but the final link to insight/intuition is also quite clear.

The value of employing this sort of thinking in analyzing the application and interaction of the full range of intangible assets is found in being able to better understand differences between industries or even between firms. KM applications have always stressed the differences between more explicit and more tacit knowledge and the implications for installing appropriate management systems. Taking the same thought a step further, installing big data systems and/or business analytics structures will also depend on circumstance. Some firms have the resources and core competencies to use data/information, and expertise with more information technology-based solutions such as those found in explicit knowledge conditions may help. Similarly, some firms will have the human element capable of the insights required for intelligence or analytics while others won't. But success with managing tacit knowledge may be an indicator of such potential success.

If we can begin to organize our thoughts and examine different circumstances in these ways, we can provide more eclectic, strategy-based recommendations for managing the full range of intangible assets. Further, the differences we see across industries may be more readily explained. Indeed, the gap between KM and IC scholarship and the work on human capital in strategy research might be narrowed. This type of structure better explains concepts like general vs. firm-specific knowledge and star systems as it differentiates even further between the structured and the personal (Nyberg, et. al., 2014; Ployhart, et. al. 2014). An opportunity exists to build a more comprehensive theory of how intangibles work in firms by reconsidering how data, information, explicit and tacit knowledge, and insight/intuition/intelligence fit together.

FUTURE RESEARCH DIRECTIONS

Abundant research opportunities exist in big data generally, as noted earlier, it is an underdeveloped field in terms of scholarship. Practice is well ahead of the academic literature. But the key point of this article concerns the overlap between the distinct fields of knowledge management, intellectual capital, competitive intelligence, and, now, big data and business intelligence. While big data serves to remind us that not all valuable intangibles are found in what we define as “knowledge,” there is also much that could be transferred from what we know about knowledge management as more organizations move to add big data programs.

In particular, both KM/IC and competitive intelligence have developed a substantial literature on understanding the nature of knowledge and using appropriate tools to manage it. Whether knowledge characteristics (tacit/explicit, complexity, specificity) or knowledge type (human, structural, or relational capital), there are undoubtedly extensions that can be made to big data or business intelligence, particularly when looking at mechanisms to develop knowledge/data (communities of practice, knowledge markets) or analyze them (war games, scenario planning, shadow teams). Similarly, the people issues surrounding use of such systems (trust, incentives) and related issues (social capital, social networks) could also be useful in this new application.

And, in the other direction, increasing use and development of big data should improve the practice of KM/IC and competitive intelligence. Although not as advanced, there is no reason valuable knowledge and intelligence cannot be enhanced by the analysis of data and information. The value of intangibles can only be enhanced by learning to use an even wider range of inputs, and there is interesting work to be done on how to add data and information analysis to existing KM structures.

CONCLUSION

This article has focused on some of the similarities and opportunities for cross-fertilization between the existing disciplines of knowledge management, intellectual capital, and competitive intelligence and the newer field of big data/business analytics. Previous work has shown opportunities for learning between the existing fields. Bringing big data into the picture extends the opportunities in important ways in a new field drawing considerable interest from both practitioners and scholars. In particular, big data widens the net for potentially useful inputs, including data and information that has yet to develop into the knowledge traditionally developed by KM systems. Big data practice also reinforces the importance of actionable intelligence, recognized in competitive intelligence practice but not always in KM/IC.

At the same time, big data installations will undoubtedly run into some of the same growing pains experienced by KM/IC and competitive intelligence over the years. Establishing the right-sized initiative, with the right price tag, and with the right tools/techniques has shown itself to be an important consideration in the more mature disciplines. Beyond the IT structure, working out the people issues, with concerns about trust, motivation, usefulness, and other such matters has also proven to be an important issue. The underlying social capital and social networks can also be critical. Finally, the importance of protecting intangible assets, not only in terms of IT and data security but, again, from the perspective of the people involved will likely also prove to be a concern. The existing disciplines have depth in all of these areas, in both in scholarship and application, proving a useful guide for those willing to learn from past experience.

KEY TERMS AND DEFINITIONS

Big Data: Large amounts of data generated and stored by an enterprise, often in the areas of operations, transactions, and/or communications.

Business Analytics/Intelligence: Analysis of big data for strategic, tactical, and/or operational insights.

Competitive Intelligence: Gathering and analyzing data, information, and knowledge relating to a competitor or related topic, resulting in actionable intelligence.

Data: Observations.

Information: Data in context.

Intellectual Capital: Knowledge assets of the organization, commonly thought to be made up of human capital (job-related knowledge), structural capital (persisting knowledge assets of the organization such as systems or culture), and relational capital (knowledge relating to external entities).

Intelligence: Actionable insights.

Knowledge Management: Methods to identify, organize, and leverage knowledge assets through further distribution and sharing.

Knowledge: Know-how or expertise.

Business Intelligence

B**Richard T. Herschel***Saint Joseph's University, USA*

INTRODUCTION

Big data is one of the most commonly written about topics in today's press. Routinely we are bombarded with reports about how much more data there is, how much more is now able to be captured, how many new sources it comes from, and how it is being used to in new and novel ways at the expense of our privacy. As Bernard Marr (2015) asserts it is a topic that is discussed in boardrooms, business publications, and the mainstream media, because big data provides new insights into everything. Big data encompasses traditional sources of structured transaction data that is now supplemented by mass quantities of unstructured data. This data is processed by new, inexpensive, and faster hardware that is then scrutinized by new and more advanced analytics that provide organizations with more in-depth insight into their operational environment than ever before.

The role of business intelligence [BI] is to seek value from data. Today, BI combines text, video, voice, location data, social media, and any other new source of data with traditional data sets in order to learn about, interact with, and predict what is happening so that the organization can respond as fast as possible to whatever it perceives is the opportunity that the data reveals. BI deals with imperfect data that is oftentimes ambiguous, but which is available on a vast scale. As a result, Mayer-Shonberger and Cukier (2014) assert that the effect is that the extraction of value from big data is analogous to a treasure hunt. That is, organizations are scrutinizing big data to learn what is happening, without necessarily needing to understand why. They argue that in a big data world, correlations supersede causality, because

the data is simply used to discover patterns and correlations in the data that offer novel and invaluable insights. The more data you have the better the insights. The underlying premise for BI then becomes this: the more data an organization can capture, the better the data-driven probability of understanding what is happening, and the faster you can respond to this insight. This means then that actions taken in BI are often based on an organizational/system confidence level in the analytic assessment of what the data suggests without any clear understanding of the root cause.

Big data would appear to many to be more about systems, and less about people. Certainly people are important because they are themselves a major source of big data fodder and it is oftentimes people's behavior that big data is trying to affect. Nevertheless, big data also is dependent on people because people must inevitably be responsible for how data is used, how it is managed, and for the consequences of the decisions made when using it.

This paper is intended then to remind us that big data is not simply something that data, systems, and analytics make happen and that we are somehow divorced from it and not responsible for unintended consequences. Instead, prudence would require that since we have unleashed big data, we have to somehow insure to the best of our ability that if we can't control big data we can at least use common sense in how we approach it and manage it.

BACKGROUND

The amount of data in our world has exploded exponentially such that data, especially unstructured data, is now referred to as "big data". Where

DOI: 10.4018/978-1-5225-2255-3.ch082

measures of data were once gradually evolving from megabytes to terabytes, the sudden phenomena of big data accelerated these measures to volumes expressed in petabytes (1,024 terabytes) or exabytes (1,024 petabytes). The new influx of data is derived from billions to trillions of records of millions of people—all from different sources (e.g. Web, sales, customer contact center, social media, mobile data and so on). The data is typically loosely structured and often incomplete.

Big Data is the natural result of four major global trends:

1. Mobile computing
2. Social networking
3. Cloud computing
4. Moore's Law [processing power doubles every 2 years]

A lot of big data is derived from cell phone traffic and social networks, with much of it being stored in the cloud. The amount of this information grows almost exponentially as people routinely interact with companies and each other via wireless and wired networks as a matter of course.

The data being transmitted and captured from these transactions has become a key basis of competition, underpinning new waves of productivity growth, innovation, and consumer surplus, according to research by MGI and McKinsey's Business Technology Office (Manyika, Chui, Brown, Bughin, Dobbs, Roxburgh, & Hung Byers, 2011). From the standpoint of competitiveness and the potential capture of value, big data has had a substantial impact. Today, organizations leverage data-driven strategies to innovate, compete, and capture value from deep and up-to-real-time information. Hence, leaders in every sector are confronted with the need to grapple with the implications of big data in a quest to capture and harness its potential value.

The significance of big data to an organization falls into two categories: analytical use, and enabling new products. Big data analytics can reveal insights hidden previously by data too costly to

process, such as peer influence among customers, revealed by analyzing shoppers' transactions, social and geographical data. Being able to process every item of data in reasonable time removes the troublesome need for sampling and promotes an investigative approach to data, in contrast to the somewhat static nature of running predetermined reports. Hence, big data expands BI's data-driven decision-making opportunities.

In their book, "Big Data, Big Analytics: Emerging Business Intelligence and Analytic Trends for Today's Business", Minelli, Chambers, and Dhiraj (2013) present significant evidence supporting the value and justification for businesses to be 'big data-driven'. Minelli et al. define big data as data that goes beyond the traditional limits of data along three dimensions: volume, variety, and velocity. Volume is important because in the past, business use cases and predictive analyses were restricted because the data volume utilized was limited due to storage or computational processing constraints. However, with big data technology removing these constraints and allowing the use of unstructured data and more transaction data for larger data sets, Minelli et al., assert that organizations can now discover more subtle patterns that can lead to targeted actionable decisions, or allow them to factor in more observations or variables captured over a longer period of time into predictive models. Variety of data refers to the different types of data now available for analyses. Instead of simply using structured text or numbers, unstructured text, audio, images, geospatial information, and internet data are now captured and able to be analyzed. Velocity is about the speed at which data is created, accumulated, ingested, and processed. Minelli et al., state that since this data is now readily available, organizations pursue technologies to help them immediately process this information for real-time analytics-based decision-making.

IBM's Institute for Business Value (2013) added a fourth dimension to describe big data called *veracity*, or the uncertainty of data. They argue that the need to acknowledge and plan for uncertainty is a dimension of big data that has

been introduced as executives seek to better understand the world around them. With data types changing constantly, and data collection increasing in quantity and speed, the quality of the data is a concern to be managed.

SAS Institute (2015) proposes two more dimensions as important to the understanding of big data:

1. **Variability:** In addition to the increasing velocities and varieties of data, data flows can be highly inconsistent with periodic peaks. Daily, seasonal and event-triggered peak data loads can be challenging to manage, but they are even more so with unstructured data involved.
2. **Complexity:** Data now comes from multiple sources. And it is still an undertaking to link, match, cleanse and transform data across systems. This requires that organizations increasingly focus on connecting and correlating relationships, hierarchies and multiple data linkages or data can quickly spiral out of control (SAS Institute, 2015).

In essence, big data has now become a kind of capital. Because of its breadth, volume, richness, and timeliness, many firms see it as an important asset that when harnessed, can be used for creating new products and services. It is a capital on par with financial capital. Oracle (2015) asserts that for CEOs to realize its potential, they must secure access to big data and then increasingly exploit its use before their competition can.

ISSUES, CONTROVERSIES, PROBLEMS

The rapid rise of the big data phenomena presents a plethora of new challenges for CEOs and their organizations. For example, IDG Enterprise Big Data research (IDG, 2014) conducted a survey with the goal of gaining a better understanding of organizations' big data initiatives, investments

and strategies. Their key finding included the following:

- Organizations are seeing exponential growth in the amount of data managed.
- Companies are intensifying their efforts to derive value through big data initiatives.
- CEOs are focused on the value of big data and are partnering with IT executives who will purchase/manage/execute the strategies.
- Organizations are investing in developing or buying software applications, additional server hardware, and hiring staff with analytics skills for big data initiatives.
- Organizations are facing numerous challenges with big data initiatives, especially the limited availability of skilled employees to analyze and manage data.
- Half of respondents indicated there is no clear thought leader in the big data solution space (IDG, 2014).

Clearly big data is getting organizational attention. However, the above findings suggest that firms are struggling to manage how they adapt to big data challenges on a number of fronts while at the same time facing some urgency in trying to harness its value.

Some of the challenges they face were unanticipated. For example, access to new sources of big data, including mobile data, social media content, and location services information means that businesses are collecting an extensive amount of personal information about their customers. This means that:

- Businesses now have the capacity to leverage more personally identifiable and sensitive information for competitive advantage.
- There is a dramatic surge in identity theft that has the potential to compromise secure transactions.

- Firms must address the development of sophisticated technology to exploit data security vulnerabilities.
- Consumers are increasingly aware and concerned about the collection, use, and disclosure of personal information.
- Legislators are responding to consumer concerns by restricting access to and use of personal information (Herschel, 2015).

An obvious conclusion is that big data can cause big headaches if organizations don't have a plan to manage it in the midst of rapidly evolving circumstances. To address these issues, firms cannot rely simply on software solutions, hardware fixes, or other IT initiatives. Instead, management is going to have to take a deep breath and consider pursuing broader organizational solutions to address some of these issues.

SOLUTIONS AND RECOMMENDATIONS

To determine how well organizations are taking advantage of big data, the IBM Institute for Business Value (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013) surveyed 900 business and IT executives from 70 countries. Their analysis of the survey results enabled them to establish nine levers that differentiated companies who are best able to derive value from big data from those who aren't:

1. **Culture:** Availability and use of data and analytics within an organization.
2. **Data:** Structure and formality of the organization's data governance process and the security of its data.
3. **Expertise:** Development of and access to data management and analytic skills and capabilities.
4. **Funding:** Financial rigor in the analytics funding process.
5. **Measurement:** Evaluating the impact on business outcomes.
6. **Platform:** Integrated capabilities delivered by hardware and software.
7. **Source of Value:** Actions and decisions that generate results.
8. **Sponsorship:** Executive support and involvement.
9. **Trust:** Organizational confidence (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013).

This list affirms that many of the issues surrounding big data are issues of organizational management. That is, culture, expertise, finance, performance measurement, value creation, leadership, and trust are all traditional management concerns. What has changed, is the suddenness of big data, the new technologies that have been created to process it, and the impact it is having on the ability of firms to react to it in an effective and timely manner. In essence, big data has become an aggressive, persistent, and pervasive irritant that is able to expose organizational data management limitations. Therefore, one of the easiest ways to understand an organization's shortcomings in the handling of big data would be to examine how capable they currently are in dealing with data management - period.

In his book on data management, Tony Fisher (2009) argues that data governance programs are essential for enterprises to experience success with business intelligence initiatives. As companies grow and look to incorporate additional data sources such as big data it is vital that they have an effective data governance process in place. To assess this, Fisher created the Data Governance Maturity Model that encompasses four phases: Undisciplined, Reactive, Proactive, and Governed. Each phase represents a different risk versus reward profile and as a company progresses through the model they increase their ROI for business intelligence while simultaneously reducing risk for the company. Each of these stages is defined below:

- **Undisciplined:** At the initial stage of the Data Governance Maturity Model, an organization has few defined rules and policies regarding data quality and data integration. The same data may exist in multiple applications, and redundant data is often found in different sources, formats and records. Companies in this stage have little or no executive-level insight into the costs of bad or poorly integrated data. About one-third of all organizations are at the Undisciplined stage.
- **Reactive:** A Reactive organization locates and confronts data-centric problems only after they occur. Enterprise resource planning (ERP) or Customer Relationship Management (CRM) applications perform specific tasks, and organizations experience varied levels of data quality. While certain employees understand the importance of high-quality information, corporate management support is lacking. Studies show that the largest share of all organizations – 45 to 50 percent – fall into this stage.
- **Proactive:** Less than 10% of all companies have reached this level. The Proactive organization adopts a more unified enterprise view of data, implementing and using customer data integration and product data management solutions. In this stage, management understands and appreciates the role of data governance and data is seen as a strategic asset. Here data stewards emerge as the primary implementers of data management strategy and work directly with cross-functional teams to enact data quality standards.
- **Governed:** At the Governed stage, an organization has a unified data governance strategy throughout the enterprise. Data quality, data integration and data synchronization are integral parts of all business processes. The organization has a comprehensive program that elevates the pro-

cess of managing business-critical data (Dataflux, 2015).

These stages provide a framework for organizations to gauge how well they are progressing with their data governance, data quality, and data management efforts while also providing information as to how they can progress to improve to a higher level of Master Data Management [MDM] – a term commonly used in the marketplace to describe this framework. Informatica (2015) defines MDM this way:

Master data management (MDM) in effect turns the Data Governance Maturity Model from a framework to a methodology for improving data management. MDM, like the Maturity Model, has the goal of helping organizations to attain:

- **A Single View of The Data:** Creating a single, authoritative view of business-critical data from disparate, duplicate, and conflicting information.
- **A 360-Degree View of The Relationships:** Establishing business rules that let firms identify the relationships among the data.
- **A Complete View of All Interactions:** Integrating the transactions and social interactions that have occurred with a product, customer, channel partner, or other data element to give the organization a complete view of that customer (Informatica, 2015).

Ali (2014) states that C-suite executives are increasingly taking notice of the market opportunity for big data analytics. Organizations that deploy data analytics are, he asserts, better equipped to make time sensitive decisions, monitor emerging trends, react quickly to new business opportunities, and ultimately, maximize the ROI of real-time data better than ever before. If data is being dispersed throughout the enterprise, the ability to discover or to fully leverage analytics tools to gain value and insight from data is cumbersome and inaccurate. An MDM framework therefore becomes essential to ensure that the data supporting the analytics

is relevant, timely and accurate. Inevitably then, executive support of MDM becomes essential if the organization is going to employ big data for data-driven decision-making.

Indeed, Eckerson (2014) writes that effective data governance programs must be enterprise-wide with effective programs combining both a top-down and bottom-up approach to data management. He argues that organizations must have a data governance methodology like MDM in place to enable this. Moreover, he recommends that senior management establish a data governance office (DGO) with a full time staff and a data governance officer. Eckerson proposes that the DGO should work with a data governance steering committee and data stewards to manage and monitor the organization's data governance program. Data stewards are employees with specific subject matter expertise who assume responsibility for certifying data, managing exceptions, and applying controls to safeguard data and individual privacy. Their role is to ensure that the data management, data governance, and business and quality rules definitions are appropriate for different lines of business. Each data steward provides critical input into cross-enterprise data management policies and ensures that these policies are appropriate for the business processes and applications that support the specific lines of business that they represent. Because of the necessity for these interactions, Eckerson believes that data governance is mostly about communications and change management where many conversations are routinely occurring among many people in different parts of the organization to insure that business processes flow smoothly and efficiently.

Brown, Court, and Willmott (2013) state that effective data management requires executive buy-in for data governance efforts to succeed, because capturing the potential of data analytics requires a clear plan that establishes priorities and well-defined pathways to business results and developing that plan requires leadership. This presumes that executives clearly understand and endorse the use of big data, that they comprehend what data

governance is and how important their role is to insuring its adoption and diffusion, and that they fully comprehend that effective data governance comes at a cost: organizational change. This means that senior management must be intimately involved in crafting the blueprint that encompasses the vision, strategy and requirements for the organization's big data journey. This blueprint should define the scope of big data utilization and management within the organization, prioritize the key business challenges that big data will address, provide a schedule for dealing with these challenges, and provide a plan for developing or acquiring the people and technology resources needed to get the job done (Balboni, Finch, Rodenbeck Reese, & Shockley, 2013).

To be effective, big data solutions must be based on business requirements and address the infrastructure, processes, data sources, and skills required to support this business opportunity. To accomplish this, senior management must establish a plan and process that is consistent with the organization's culture and guiding principles such that these are subsequently reflected in the organizational data governance activities. Management must ensure that data governance is viewed as a continuous and systemic endeavor that is woven into the fabric of the organization's structure and processes rather than being established as an ad hoc response created to deal with a novel 'big data' phenomenon.

Executive understanding and support of MDM-type big data governance processes should reflect the conscious realization that they will need to develop, acquire, and retain a strong core of human capital. Qualified data stewards, for example, must be identified and selected. These individuals, through their actions, reflect the values, policies, and procedural requirements that are derived from senior management. In a big data world, executive leadership is also needed to find, develop, and retain strong analytical talent. Analysts with strong mathematical, statistical and computer science roots, as well as familiarity or expertise in areas such as data mining, data visualization,

optimization and simulation, text analytics, and predictive analytics are going to be required to harvest meaning and value from big data. The problem is that there is a severe shortage of this talent. For example, McKinsey & Company (2015) asserts that only 18 percent of companies believe they have the skills to gather and use data effectively. And this becomes more troubling when they further state that the United States alone faces a shortage of 140,000 to 190,000 people with analytical expertise and 1.5 million managers and analysts with the skills to understand and make decisions based on the analysis of big data. IDC's (2014) estimates are also daunting, stating that in the U.S. alone, there will be 181,000 deep analytics roles in 2018 and five times that many positions requiring related skills in data management and interpretation. Leadership is required to find creative means for acquiring the requisite BI talent that organizations need.

Dyché and Nevala (2015) discuss key issues where executives have to be careful in addressing big data and data management issues. These issues include failing to define what data governance is, not approaching big data and data management in a progressive and systematic manner, failing to design data governance teams properly, treating data management as a project, and overlooking organizational cultural issues. They note that issues needing to be addressed by data governance and big data are far-flung and pervasive, ranging from arbitration of cross-functional data usage to information privacy, security, and access policies. As a result, executives need to understand that if they look to implement data governance and other big data initiatives too quickly, the intended results may well be stymied quickly by role confusion, prioritization debates, project development problems, and resistance from the incumbent culture. When these issues are combined with the plethora of other issues that big data creates, it becomes essential that executives be cautious and level headed when evaluating how data management efforts are being constructed and deployed in their organizations.

FUTURE RESEARCH DIRECTIONS

B

Research into the impact of big data needs to expand its focus to explore in more depth how BI is affected by management's ability to cope with data governance, analytics talent recruitment, and other peripheral issues. MDM and data governance activities appear to be sensible techniques for managing data, but it is clear from the statistics that not all of these practices are being effectively adopted and deployed. Understanding the rationales for the adoption and leveraging of data management techniques as well as their consequences provide insight into managements understanding of big data and their ability to exploit it.

Managing big data requires common sense. Common sense is derived from the way you think, intuition, and experience. It suggests the ability to think and behave in a reasonable way and to make good decisions. It incorporates such attributes as the ability to think rationally, to act purposefully, and to deal effectively with your environment. Common sense dictates that firms need to be cautious with big data so as not to compromise their BI efforts and data-driven decision-making. I argue that given the technologies, data management techniques, and advanced analytics that impact BI, we need to also focus on better understanding how big data affects management common sense and vice versa. That is, we need to look behind the curtain to learn more about the management actors on the big data stage.

CONCLUSION

Big data is not a cure-all, and it is inherently filled with noise and uncertainty. It has tremendous potential if people approach it the right way. What is important is that there be thoughtful leadership in organizational efforts to manage its capture, storage, sharing, and use. Big data is not just about data and technology. It is clearly about organizational changes in attitudes and functions. And collectively all of these efforts focus on one

thing – gaining better business intelligence for decision-making.

All Analytics (2015) notes that with big data, it is important to understand not just what data you have and what the data says, but also how specifically the data will be used in the business environment. The article asserts that:

- Companies can miss opportunities because line managers may not have been shown how data can help them do their jobs better,
- Management and analytics teams may need to examine existing problems, workflows, and processes to also understand how data might help them do their jobs better, and
- Organizations need to understand why it is essential to incorporate the human element into their planning processes for analytics initiatives.

Inevitably, business intelligence is about people, not just data and analytics. People establish and employ the processes and procedures where data and analytics are deployed and through which decisions are made. Hence, understanding the reasoning underlying these processes and procedures [and their consequences], and fleshing out the relevant data and processes that will help people make better data-driven decisions is important. However, in doing this we must also ensure that people can understand and appreciate the value of any changes being made. This means that we need to look hard and examine, document, and improve the interaction between human behavior and the goals of business intelligence in a world troubled by big data.

KEY TERMS AND DEFINITIONS

Big Data: It is a popular term used to describe the exponential growth and availability of data, both structured and unstructured.

Business Intelligence (BI): It is a business management term which refers to applications and technologies which are used to gather, provide access to, and analyze data and information about their company operations.

Data Governance: It is a combination of people, processes and technology that drives high-quality, high-value information. The technology portion of data governance combines data quality, data integration and master data management to ensure that data, processes, and people can be trusted and accountable, and that accurate information flows through the enterprise driving business efficiency.

Data Steward: A data steward is a job role that involves planning, implementing and managing the sourcing, use and maintenance of data assets in an organization. Data stewards enable an organization to take control and govern all the types and forms of data and their associated libraries or repositories.

Master Data Management (MDM): It is a technology-enabled discipline in which business

and IT work together to ensure the uniformity, accuracy, stewardship, semantic consistency and accountability of the enterprise's official shared master data assets. Master data is the consistent and uniform set of identifiers and extended attributes that describes the core entities of the enterprise including customers, prospects, citizens, suppliers, sites, hierarchies and chart of accounts.

Unstructured Data: Unstructured data (or unstructured information) refers to information that either does not have a pre-defined data model or is not organized in a pre-defined manner. Unstructured information is typically text-heavy, but may contain data such as dates, numbers, facts, or video content as well.

Improving Competitiveness Through Organizational Market Intelligence

B**George Leal Jamil***Informações em Rede, Brazil***Leandro Rocha Dos Santos***In3 Inteligência de Mercado, Brazil***Cecília C. Jamil***Stockholm University, Sweden*

INTRODUCTION

Market intelligence (MI) is a concept that results, in its implementations, in real opportunities for knowledge management in organizations. In an initial view, MI can be regarded as a cyclic process to deliver knowledge for strategic marketing decisions, considering typical organizations of a defined sector as its final users. As organizations, mainly corporations, must not only react to external factors or phenomena, but also try to lead its sector proposing and executing innovative plans and differential strategic positioning, MI is a modern and cooperative approach which can produce consistent bases for such planning abilities (Boblitz, 2006; Porter, 2008; Mintzberg, Ahlstrand & Lampel, 2009; Kim & Mauborgne, 2015). Market intelligence is affirmed as an organizational continuum that aims to answer typical decision problems faced by firms when competing in actual business environments (Van Kesteren, 2012; Jamil *et al.*, 2012).

This article aims to detail MI concept, working from theoretical point of view through literature and adds a practical approach on studying real cases of market intelligence potential applications. As MI is a multidisciplinary context, its conceptualization also provokes perspectives for research from other scientific fields, as Information Science, Systems and Management, Computing

Science, Human resources management, Strategy, Marketing, among many others.

BACKGROUND

Strategic planning and execution are two main contexts where market intelligence is definitely relevant for critical decisions, motivating the following evaluation as the start of this theoretical work.

Strategic Decision Scenarios and Its Demands for Continuous Knowledge

Strategy formulation and execution are knowledge-dependent tasks, demanding for its continuity reliable and updated knowledge availability (Jamil *et al.*, 2012; Johnson, 2012; Dimitrios, Sakas & Vlachos, 2013).

Strategic marketing decisions are the objective of the MI process, as the knowledge provision aims to solve problems, allowing decisions with clearer risk delimitations and implementation results with better customer aggregated value perspectives, attending to the basic organizational marketing demands (Kotler & Keller, 2005; Schiffman & Kanuk, 2010; Ferrel & Hartline, 2010; De Man, 2012). Typical decisions of strategic marketing processes that can benefit from market intelligence process are:

DOI: 10.4018/978-1-5225-2255-3.ch083

- Product line configuration and distribution,
- Pricing,
- Advertising and general communication,
- Differentiation as a value-based strategy, and
- Marketing channel analysis.

As examples of knowledge needed in usual marketing decisions it can be perceived: consumer behavior details, demographic perspectives and constraints, customer reaction to distribution forms and communication, distribution channels performance and financial performance for all productive chain components. Knowledge provided for marketing strategic planning will allow any organization to develop its practical, tactical-to-operations plans, which will, at the end, specify the real work to be executed, aligned to those strategic views and propositions.

Data, Information, and Knowledge

Davenport & Prusak (2000), Tuomi (2000) and Lucas Jr. (2005) defined not only the concepts of data, information and knowledge but also its relationship and integrated application views. Data is considered as an absolute value that can be obtained directly from a measurement activity or collected from an automated source. It shows flexibility to communicate, as it can be easily processed by automated instruments and machinery, but lacks more profound meaning, as it is almost impossible to deduce more from the context or process it was created, being just an instantaneous observation of a reality. From these and other authors, information is conceptualized as a collection of correlated data added with context, providing a better condition for deciding, but offering more complexity to be treated or processed. Information increases decision capabilities, but demands additional work to be finally applied, as additional work must be conducted to assure its homogeneity and coherency (example: measurements – data – were collected referring to the same system and / or context).

Finally, knowledge is composed through collection of information, including descriptions of the processes which produced that information. Knowledge allows maximum decision capabilities, for example, enabling even prediction capabilities (Davenport, 2000; Jamil, 2005; Nonaka, 2008, Badia, 2014). But on the other hand, knowledge is difficult to manage, communicate, questionable to be stored and critical to be shared, resulting in the need of a specific process to treat it, defined as knowledge management (Jamil, 2001; El-Bashir, Collier & Sutton, 2011). This fundamental area of conceptual relationship is being significantly treated, as the “big data” phenomenon is increasingly perceived by entrepreneurs and socio-political actors, calling additional attention to the process of “knowledge generated from data” which proves how important is to observe data, information and knowledge in an organizational context for decisions such as strategic marketing planning (Ohata & Kumar, 2012; Park, Huh, Oh, & Han, 2012).

Market Intelligence

Derived from many areas, intelligence is another concept that motivated various studies and expressive debate. It is opportune, though, to evaluate contributions from other scientific fields and also applied practice to improve market intelligence comprehension. This approach was also applied for several authors, as Albescu and Pugna (2014), supported by almost the same fundamental concepts applied in this development.

Competitive intelligence (CI) is a process which offers an opportune complementarity to market intelligence, although it is possible to find some confusion and lack of delimitation in some approaches of these two concepts. SCIP (2012) defines competitive intelligence as “A process of monitoring the competitive environment and analyzing the findings in the context of internal issues, for the purpose of decision support”. Kahaner (1998) and Miller (2002) defined it as a process related to strategic problems solution,

configuring CI as an organizational that has the goal to provide better decision support specifically for higher executive levels in organizations. It is important to notice that as a process primarily designed to produce knowledge from external environment interpretation, CI offers an objective response to a very precise problem, usually proposed in a formulation or revision of a strategic plan. It is so a managed cycle which is ignited by a strategic problem, held in order to provide a punctual, detailed, precise and objective to that problem (Makadok & Barney, 2001).

Market intelligence, on its way, composes internal, sectorial (external, but correlated by internal organizational configurations) and external sources to produce specific, focused knowledge to strategic marketing contexts and decision making guided to implement aggregated value positioning (Jamil *et al.*, 2012; De Man, 2012; Jamil, 2014). Finally, the convergence of strategic results of both processes – CI for strategic decision, such as those in planning and executing strategies and MI for marketing strategic decisions – also allows to understand how they can be complementary and interrelated, reiterating that market intelligence has a more practical, applicative, “to the market” objective as it is designed to support a connection between organizational strategy formulation and answers provided by strategic marketing decisions (Johnson, 2012).

As another contribution for MI conceptualization, “artificial intelligence” (AI) was proposed early as in 1950 decade, as an academic subject, sometimes related to philosophy or, alternatively, understood as a computational engineering support for automated or robotic system, as presented by John McCarty in 1956, in a conference at Dartmouth College. It turned out to be a provocative area that motivated computing, mathematic, physics and other areas’ specialists to develop theoretical and practical studies. From some contributions of artificial intelligence it is possible to understand and perceive more comprehension about this vision of intelligence: a continuum that promotes progressive and adaptive learning

absorbed from the reality, transforming it in rules resulted from accumulative knowledge created (Russel & Norvig, 2009). It is interesting to note that this accumulation of knowledge that compose rules to be further applied by one organization can also be considered as a registering of knowledge, explicitly transformed in contents that could be applied, developed, integrated and transmitted (Nonaka, 2008). As it was suggested for robotic and automated or controlled environments, AI is a form to codify predictable knowledge for repetitive application, with many improvements that can occur from continuous cycles of process (Hubber, 1990; Weiss & Verma, 2002; McAfee & Brynjolfsson, 2012).

Finally, from information technology (IT) and computing science fields, “business intelligence” (BI) arises as a relevant and broadly discussed concept. It is used for many interpretations of tools, techniques, methods and integration of resources oriented to produce specific knowledge from disperse sources of information and data, as analyzed by Inmon, Strauss & Nishloss (2008) and Kimball & Ross (2010). The IT literature concentrates predominantly in technical issues, such as implementation models, physical storage, database structuring and integration. From this point of view, intelligence comes from technological arrangements, which offers not only the mechanisms for its development, correlation between logical models to physical implementations, but also for knowledge codification, process modeling and implementation and knowledge communication and distribution (McAfee & Brynjolfsson, 2012; Courtney, 2013; Jamil, 2014). Another special aspect is integration, as the business intelligence usually is based on an infrastructure that is implemented through an associated arrangement of organizational resources, not regarding aspects such as cyclic updates or evolution, but thinking it as a solution-driven knowledge provider (Cao, Zhang & Liu, 2006; Kimball & Ross, 2010; El-Bashir, Collier & Sutton, 2011; Hoffman, 2013).

Completing this conceptual approach, market is a keyword that has to be noticed. As a con-

ceptual focus, market defines the objective for continuous knowledge treatment and production for decisions. Market intelligence is a continuous process that allows the production of knowledge from data and information in order to be applied for strategic market decisions, or, better defining, strategic marketing planning (Chen, Chiang & Storey, 2012; Vavra, 2012; Dimitrios, Sakas & Vlachos, 2013).

Considering that data and information are spread over a value-aggregated chain and MI produces knowledge to be applied for sectorial strategic marketing decision on plans, it can be proposed, from those and other references, as the following continuous process, cycle definition:

- **Aggregated Chain Value Analysis:** For an overview of the organizational arrangement where the MI cycle will occur and have its results applied.
- **Data and Information Diagnosis:** where business sector contents of data and information are evaluated to constitute a model that represents what is available for initial process design.
- **Knowledge Diagnosis:** To conceive, initially, what are the main contents of knowledge demanded by typical market competitors, for decision taking in their strategic marketing planning work.
- **MI Continuum - Process (Modeling and Implementation):**
 - **Planning:** As a start / stop point of every cycle, it is a step of planning next cycle execution – resource allocation, pre and post requirements, deliveries, risks, etc. – based on the last cycle execution.
 - **Collection:** Gathering of data and information from organizations of the sector analyzed. External sources, as government and agencies, research institutes and other partners, if diagnosed as essential or opportune, are also collected.

- **Validation:** Normalization and correction of data and information collected, as those sources can produce different or mistreated contents that have to be leveled to become understandable as similar for cyclic analysis.
- **Processing:** Usage of business rules, logic modeling, statistical and mathematical analysis applied to data and information to produce specified knowledge contexts.
- **Sharing:** Results sharing of the processing that are delivered, presented, transmitted to interested market players for further application in their decision scenarios.

This definition, encompassing the first conceptual affirmation and the structure depicted above constitutes the theoretical background of market intelligence, being defined by the Fig. 1, detailed below:

In the following, an analysis of practical cases is held, validating this framework.

MARKETING STRATEGIC DECISIONS: CASES FOR MARKET INTELLIGENCE PROCESS APPLICATION

This section intends to consolidate the conceptual base discussed before through case studies where market intelligence played a relevant role as conceptualized. Each of the following case studies were worked for commercial and marketing sectors, with firms grouped as *informational associations*, according to Marchand, Kettinger and Rollins (2001), taken or observed as a group of organizations that present similar informational behaviors in terms of its problems, needs, infrastructures, research methods and processes.

Figure 1. Market intelligence cycle

Case 1: International Expansion Decision

In the pharmaceutical sector, productive arrangements are complex and can be specialized by product lines, resulting in a situation where one producer can formulate different marketing strategies for different products. This complexity increases substantially as a producer intends to expand its operations abroad, commercializing pharmacies in additional regions and countries. Along with customer data – for instance those which inform consumption potential, desirable forms for payment, buying behavior and decision – information about fiscal, health sector laws and distribution issues are needed to perform a complete study in order to solve decisions as to determine where to install a factory, the optimal distribution system for final customers of one region or how to reduce costs for a competitive offer in a region already efficiently handled by a competitor.

These issues can be more clearly solved with support of a market intelligence process, being conducted by a group of firms that compete in

this sector. A sectorial market scenario description – market knowledge – can be supplied in a predicted frequency, for instance biannually, presenting knowledge contents as: market share evolution, prices evolution, shared data about distribution and sales, final customer behavior and reaction to advertisement and promotional campaigns, among many others. A continuous analysis for any player can identify more precisely where – in what country or region – there is a potential local market that could provide financial support for a factory installation, allowing it to sell locally and abroad.

Case 2: Product Launching and Positioning

Is it better to launch a new isolated product or insert it in a product line already being in offer for final customers? This typical marketing-oriented decision is critical, as a product can have its perceived value components not correctly evaluated by a final customer, depending on the way it will be sold. For steel industry, for instance, a special type of steel can be understood by automotive

industry as a specialization of an already offered steel composition or a special product, resulting from sophisticated laboratorial work, with more aggregated value.

This decision can be worked more intensively and studied in a more detailed way, if the steel industrial sector practices a market intelligence analysis that, for a period of some “buying cycles” (for instance, for some years), show how and why the final production for its customers – automobiles, in this example – was commercially successful. Analyzing its position as a part of a productive chain, one steel manufacturer can observe if automotive industry will or not perceive this special type of steel as only an additional product or a differential, more valuable one as it is being used in more competitive assemblies (such as cars, in this scenario). Each market intelligence cycle provided, in this case, knowledge about the performance of the final customer end, automobile manufacturers, which base the decision of the supplier, allowing to a better choice on how to offer the special metal artifacts developed as a new product.

Case 3: Investments in Changing Economies Planning

Many questions arise when analyzing a new market, as those usually shown in emerging economies. As it was discussed in the first example, market intelligence can provide not only historical content for knowledge production, to be completely examined, but also allow one organization to project future prospective scenarios, where a whole economic system can be better scrutinized. Complex decisions are made in order to coordinate strategic and tactical movements to start in one new market as:

- How to develop commercial arrangements,
- Predict and design financial positions,
- Implement logistics network,
- Along with human resources projection,

- Organizational structure and
- Capabilities development.

Continuous knowledge provision can be applied for prospective scenarios design, allowing an executive board to evaluate projections of revenues, costs, taxes (which are a very complex issue, mainly in some growing economies), performance and production alternatives to compose strategic and correlated tactical plans and also monitor its execution. As strategic planning guides and defines conditions for tactical and operational plans, the aligned definition provided by more precise designs of competitive conditions, resulting from a complex analysis which encompasses sectorial, governmental, competitors and value chain data and information to produce knowledge, treated by a cyclic process, allows each firm to develop and control more realistic and risk managed plans.

From the cases discussed above it is possible to understand the main benefits of market intelligence process, bringing a more objective focus and comprehension about its structure. All of those decisions, and many other that could be studied, do not essentially suffer from lack of data, or even information, instead of it is possible to preview that huge amounts of data and information are available for decision. But it is also possible to predict that these contents are shown without the needed cohesion, coherency, relationship and, mainly, a process management which make it difficult to obtain the demanded knowledge. Examples of these problems can be learned from authors of information systems areas as Laudon & Laudon (2009) and O'Brien & Marakas (2008) – or in marketing research – as Kotler & Keller, (2008) or Ferrel & Hartline (2010). Structured models for data and information acquisition, along with process definitions for its collection, validation, processing and result production – the market intelligence process definition – allow to cyclically apply knowledge to better define these issues and obtain the expected responses for decision making.

FURTHER STUDIES AREAS

In this section, some of potential fields and further studies are presented both to reaffirm the concept of market intelligence and, in the spirit of an Encyclopedia, to give perspectives to the reader to develop new and deeper studies with support of the conceptual framework reached.

Information technology has a remarkable application not only in the structure of the market intelligence process, but also to advance its development, as database models, information systems design architecture and implementation, application of user-oriented knowledge production tools and many other subjects related to this area can be better observed collaboratively (Turban, Mc Lean, & Wetherbee, 2002; Turban, Rainer & Potter, 2007; Kimball 2010; Johnson, 2012; Mahrt & Scharkow, 2013).

As suggested themes for new researches in IT area a special attention must be devoted to how to implement business models, based on market intelligence through modern IT architectures, analyzing, for instance, the introduction of mobile payment, communications and customer-oriented interactions, database services modeling and the aspects of IT support for social media environments and the “big data” phenomena, rich but still not completely deciphered in terms of scientific application researches.

Information systems (IS) design, modeling and application are other subjects, as understood both from computing science and information science point of views. As knowledge production tools based on information and data gathering, it is opportune to advance the conceptual framework studied and developed and also understand how the information systems perspectives, services, design and repercussions can be obtained or implemented, along with user reaction to this tools and processes in organizations (Jamil, 2001; Stair & Reynolds, 2009; McAfee & Brynjolfsson, 2012; Hoffman, 2013).

Clearly, as those fields are the main areas of research implied by the eventual success of a

market intelligence process, organizational strategy – involving planning, execution, relationship with tactical planning and others – and marketing – especially strategic marketing planning – are two main scientific subjects to propose advanced studies about organizational intelligence. These themes can also provide opportune methodology-supported case studies for conceptual and practical evaluations, about planning and implementing hypothetical and practical market solutions. Connecting theory to practice, this relationship enables application of various methodological approaches, such as surveys, Delphi group analysis, participative studies, qualitative techniques and so forth. The results, potentially rich for new business models implementation can be considered as some interesting repercussions from market intelligence process detailed comprehension.

Also, information and knowledge management as central themes and its repercussions around areas such as Management, Information Science, Engineering and many others can benefit from MI discussion and conceptualization.

With this study, it is expected that not only a contribution for market intelligence process itself was reached, but also a base for further studies in various areas and scientific fields, related to strategic and marketing competitive positioning can be developed, taking it as one source of conceptual base.

CONCLUSION

In this chapter market intelligence process concept was developed in order to provide its fundamental understanding and allowing its observation for further studies. As a complex, intricate and interrelated organizational process, it offers implications for many entrepreneurial aspects and tasks, allowing not only the consolidation of the past, but also projecting some future perspectives for businesses.

MI is conceptualized as a process structured mainly as a continuum that starts with the compre-

hension of the value chain of a sector, modeling of data and information that exists in one sector and relating it to the needs of typical competitive firms of one sector for knowledge to solve strategic marketing decisions. From this first level, a routinely process is designed in order to collect, validate, process data and information and produce marketing strategic knowledge allowing better level of decision for each organization that was researched.

Its implications as a modern, competition-driven and competition-oriented process to be applied by sectors with possibilities for entrepreneurial plans and actions inside or outside a market sector are expressive, favoring better strategic, tactical and operational planning and execution and in all levels, better risk management and monitoring.

KEY TERMS AND DEFINITIONS

Competitive Intelligence: An organizational process which aims helping to solve strategic problems and decisions through data and information collection, validation, analysis and results production.

Knowledge Management: A process that intends to administrate the creation, retention and registering, sharing, valuating, monitoring and application of knowledge in organizations.

Marketing: An integrated organizational discipline oriented to aggregate value for product and services, considering customers wishes and needs.

Market Intelligence: A continuous organizational process that intends to produce knowledge for strategic marketing planning, collecting data from a value-aggregate chain, validating, processing and communicating the final results in a standardized way.

Strategic Marketing Planning: A part of the marketing planning process which intends to connect the strategic goals expressed in organizational

strategic planning to tactical marketing specifications, which will lead to product or services definitions, prices, promotion and distribution.

Digital Animation for Representing Architectural Design

C

Roberta Spallone

Politecnico di Torino, Italy

INTRODUCTION

Since the late Nineties of XX century digital movies have been emerging as one of the main methods for submission of architectural designs at international competitions, public presentations and shares on contemporary masters' websites, allowing to preview buildings, spaces and urban environments before their eventual construction.

The chapter highlights how the ability to access the fourth dimension, through the construction of a sequence of images, constitutes a specific prerogative of the digital representation, which goes beyond the static constraint imposed by conventional methods of representation codified by the Descriptive Geometry in the previous centuries.

The great complexity of architectural video production has led to the birth of new professionals who specialize in modelling, rendering, animation, graphics, montage, editing and post production and work in specialist studios. In the past, this had resulted in the generation of specific and recognizable languages: the language of the design was overlaid by that of its narration, and they were not always in harmony one with the other.

The author investigates on the methods, techniques and languages of the fourth-dimensional communication of architecture, unexplored area of research thus far, already the subject of previous studies, relating them with the masters' personal poetics.

The chapter provides also analysis and critiques of several case studies collected by the author from the beginning of the phenomenon, and traces an ideal interpretation path, due both to the changing technologies and the emerging specific languages.

BACKGROUND

Digital modelling has affected the entire design process in recent years, starting with the conception through the control and communication of designs and finally to the provision of tools for building construction and then management activities. For the design stage of the process, these new modelling tools seem to have unified the constituent elements of drawing and design, reconstituting them within the etymological roots of the Latin term *designo*, the twofold meaning of which alludes to an abstract component, indicating the mental processes intrinsic to design, and another concrete component relating to the tangible operation of drawing (Garzino, Spallone, & Lo Turco, 2011).

These tools offer a possible answer to Rogers's wishes, who in 1990 said that "what is needed... is for the meaning of drawing (and therefore also the pedagogical and practical interpretation that is derived from it) not to be just the descriptive representation of an object generated by means of symbols, but for its ancient semantic value to return to it, which is summed up today by the English word design (as opposed to drawing), in which the symbols themselves contain the concept of thought, concrete intention and the design of an object" (Rogers, 1990).

Digital models have a syncretic nature which offers new opportunities to the scientific research and architectural design: tests and errors occur in a space in which our experience of problems are rendered fluid and immediate as in an architectural promenade, "3D computer models... allow more enhanced and more controlled interaction

between users and models, they are able to cover the whole range of possible models in a single system of representation” (Maldonado, 2005).

Moriconi, an earlier scholar of infographics, underlined that “through the infographic support, digital drawing simulates a hypothetical reality, goes beyond the limitations of the static and allows interaction with any type of sign. With the creation of virtual images, infographic technology represents what is perhaps the most appropriate tool for interpreting the complexity of reality” (Moriconi, 2001).

According to Manovich the rise of the movie camera as a universal paradigm for the interaction with any data which is represented on three dimensions goes back to the 1980s and 90s. Indeed he affirms that “as the computer culture is gradually spatializing all representations and experiences, they become subjected to the camera particular grammar of data access. Zoom, tilt, pan and track: now we use these operations to interact with data spaces, models, objects and bodies” (Manovich, 2011).

As a new medium, the animation of digital models requires the establishment of relationships with several disciplines such as communication sciences and cinema engineering and with technologies like that of video games and it must also pass the test of comparisons with the established conventional technologies of film production. “Considering architecture as a form of art, we might learn from other artistic disciplines, such as moviemaking (cinematographic approaches, sequencing and animation), theatre (physical expression, interaction, improvisation) and music (rhythm, harmonic variation, but also digital recording and sampling). These may expand the palette of architecture (traditionally making use of drawings, models, pictures and symbols)” (Breen & Breen, 2011).

This triggers a critical discussion on the ontological nature of films, on their narrative form and on their character of exploring human emotions, and it implies the attention of videos

of architecture to the perceptual effects produced by relations between persons and space.

Three dimensional digital models frequently constitute the basis for the production of particularly effective visualizations, using a variety of techniques, which can be exploited for different purposes. As Engeli noted, “the creation of specific messages relating to space requires an in-depth knowledge of the intrinsic characteristics to the different possibilities and to the aspects that are wished to emphasize.

An object that is viewed can be interpreted in different ways. The main parameters (light, materials, perspective) can bring out the nature of an object, work against it, reveal new information and add or hide aspects of the object” (Engeli, 1999).

Engeli also underlines the role of narration in the communication of a design: “when you talk about a design, the aim is to give the public an opportunity to identify with the object that is being presented. This is the main reason why it is necessary to tell stories about designs. In reality all architects perform a similar operation when they present design ideas, but usually it is not a capability that is used knowingly, despite the importance of that activity for the communication of ideas” (Engeli, 1999).

The producers themselves, who include multidisciplinary groups, composed of architects, graphic designers, modellers, producers and musicians, underline the importance of animations for the representation in architecture. In an old interview, Scott, Hampton, Alsop and Cocke, members of Squint/Opera, one of the most famous creative company, underlined the importance of videos in the presentation of a design: “I would like to encourage all architects to tell the story of their designs by using videos, because it is a tool which helps people to see a design in a different way. Our experience of architecture is dynamic: we move through spaces and it is precisely this aspect that a film is able to explore” (Oddo, 2004).

Taking the part of the stakeholders, also today the foresight of Gregotti, who observed that “who

has had experience like a member of architectural competition jury panels composed by different experts, knows very well which confusion has been done between the value of design and the fascination of representation considered as a painting... we will see in any year in which way video and virtual representation will act on communication in architectural competition" (Gregotti, 1995) seems to the author surely alive.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

For over fifteen years the 'spectacle of architecture' has been identified in the digital representation of space and time, especially in the animation, one of the most effective media for the prefiguration and communication of architectural design.

The author, following the development of the architectural representation from the outset through digitally constructed video believes that, with some simplification, after a first moment of the centrality of digital modelling within which paths were created or singular elements of the building were animated a following moment in which photo-realistic and hyper-realistic results were chased and another, still, characterized by the pursuit and consolidation of narrative styles, is witnessing nowadays a phase of reflection and refinement, with a return of the communication process production within the atelier of architecture, which addresses, therefore, technical choices and languages consistent with its design poetics.

The current trend, in fact, is to turn increasingly to the opportunities offered by the motion graphics, through the hybridization between static and

dynamic images of different nature, photorealistic renderings tend to be singular, as they are snapshots within conceptual dynamic views, and a search for greater deepening of content takes advantage of the development of the narration on motives, concept phases and constructive solutions.

The below developed discussion, traces, through the comments of the peculiarities of several of the videos found online (not always available even today) and collected by the author over the years, an ideal path built on some case studies illustrating the developments outlined above.

As said, at the beginning of the phenomenon the centrality of digital modelling is evident in the construction of the video.

Zaha Hadid is one of the first architects who use the digital tools for the design, presentation and communication via video of the project. Central themes of her poetry, such as dynamism, fluidity, transparency, found a solution to the problems of design and representation in the digital modelling.

Also the animations of the three-dimensional models offer an opportunity to overcome the two-dimensional characteristics of her drawings and paintings and to move around buildings generated by the computer while they are still in the design phase (Schumacher, 2004). A video realized in 1999, the first that the author was able to find, in which the techniques of animation of three-dimensional model are used in the project of architecture, shows the spatial characteristics of the architectural competition proposal for the Casino and the Grand Hotel in Lugano submitted by Hadid. In the short video (0:58), produced by the computer graphics studio Neutral, which is also one of the pioneers of the specific professional field, a lava flow cools and consolidates into a new architectural form that wraps the existing

Figure 1. Zaha Hadid, Casino and Grand Hotel in Lugano

Source: Movie by Neutral (0:58), 1999

buildings. The model is rendered with only two colours, red and white, in order to resume the metaphor of lava and ice, in complete harmony with Hadid's the figurative language.

In subsequent years, the improvement of the techniques and digital tools accompanies the transition from animation resolved within the conceptual modelling to an extreme tendency toward photorealism.

The availability of software used in computer-gaming, along with the launch of YouTube in 2005, promotes the proliferation and spread of design representation through video, in particular in the field of international architecture competitions, in which usually it becomes one of the mandatory requirements, in public presentations and in self-promotion of the main architectural studios through websites. The tendency to create photorealistic images aspiring to become perfect copies of reality establishes itself at this stage, in which rendering engines, textures of materials and systems for setting the lights are improving.

The video for the project by Christian de Portzamparc in the competition for the headquarters of the Region of Rhône-Alpes in Lyon (2006) describes a building in an urban scale, a complex designed as a block, a place that can be enjoyed by the community in democratical and active way. The project won because of its elegance, fluidity and rigor and the particular suitability to the site (Cardani, 2006). In the video (3:12), composed by the studio Bartproject, a virtual man takes viewers into the building suggesting the functions of the different spaces through the movements of the body and emphasizing the role of the building as a business and trade centre. The constant speed of the virtual camera movement simulates the human walking. The video uses a communicative style,

typical of Bartproject, which combines shooting extrapolated from the reality with a hyper-realistic rendering that overlaps transparent figures symbol of an ethereal humanity in motion. The animation shows the transparency and openness of the interior spaces - the monumental entrance, the patio, the exhibition space and the room for debate, all designed to minimize the power consumption.

Architectural competition for the *Musée des Confluences in Lyon*, won by Coop Himmelb(l)au in 2001, awards a project aimed at the needs of information-society: to make perceivable current knowledge to a broad public in a process of constant change.

The concept, named Crystal and Cloud, combines a hard space, the crystal rising towards the city, conceived as an urban space and an entrance hall for visitors, and a soft space, the cloud intended by the designers to hide the knowledge of the future (Coop Himmelb(l)au, 2003). A short movie presenting the project has been included in the Coop Himmelb(l)au website, since 2007. This was probably the basis for the longer and richer educational movie now present in the Musée des Confluences website which is also enriched by an interactive virtual visit with 360° panorama views in the principal rooms.

The longer movie (7:30), produced by Isochrom in 2006, starts exploring the area of Confluences by an aerial view, first zenith and then perspective, which shows a wide urban tissue extended to the town hall, modelled with simple volumes and rendered as a plaster model lit by natural light. As the approach is made from the river to the building, the model takes on greater realism and the movement of the camera transforms into a walk through towards and inside the building under design. A virtual person guides the observ-

Figure 3. Coop Himmelb(l)au, Musée des Confluences in Lyon

Source: Movie by Isochrom (7:30), 2006

ers through the main halls to the different floors and invites them to appreciate the architecture and examine the main collections by the way the shots are framed. During the tour the visitors meet “Crystal and Cloud” which characterize the shape of the building. The model is realistically, but delicately, rendered with a particular focus on bringing out the quality of the materials, transparencies, reflections and opacities and interactions between the materials and the lights. A few blobs of warm colours attributed to the entrances of some halls, arousing the curiosity to enter them, and to secondary animation elements, emerge in the interiors in cold colours, all ranging from white to grey and blue.

In the following period there is a passage from the technical virtuosism to the research and consolidation of narrative styles.

This step intended to prevent the technocratic homologation by the software, and led the video producers to create personal and recognizable narrative languages. As stated by the following three case studies, this choice anticipates the current developments.

The submission by Steven Holl for the international architecture competition to design the future Musée du Louvre-Lens in the north of France, launched in early 2005, is a building in which the idea of a walk through time organizes the plan of the new museum according to a linear

time increment along the rectangular frame, which is crossed by cyclical time (represented by the arcs) in short circuits and different access points.

The competition animation (4:00), made by Neutral, deepens the concept ideas, showing the aquarelle sketch drawn by Holl as the basis for the three-dimensional geometric construction which develops the idea of intersection between linear time (a parallelepiped) and cyclical time (four cylindrical rings cut to make four arcs). When the geometries become buildings, the parallelepiped appears as a hard block of bricks and the arcs as light curtains of glass. The architecture, surrounded by the green, is connected to the built city in which it is wedged. The new museum and the settings are modelled and soft rendered. The camera movement, characterized by constant speed, guides the spectators outside (by a fly trough) and inside (by a walk trough) towards the knowledge of the design. Therefore most of the animation is produced by modelling software, with consequent use of bigger time.

The proposal for the invited architectural competition for a new library in Utrecht (2008), presented by 3XN, describes a multifunctional building suitable to house a library and a cinema with residences, shops and cafes. In this way, the cultural centre could be enlivened by various activities throughout the entire day. The architects' goal is to preserve the existing idea of public

Figure 4. Steven Holl, Musée du Louvre-Lens

Source: Movie by Neutral (4:00), 2005

Figure 5. 3XN, New library in Utrecht

Source: Movie by Cadpeople (3:30), 2008

life in the area, while the new building should be in function as an anthill, of which the shape resembles, characterized by multiple fronts, and should be a new meeting place for the entire city.

The 3XN claims to be deeply involved in the digital revolution (3XN, 2008) and this seems to reverberate in their choices of projectual communication, entrusted to the studio Cadpeople, demonstrating the close cooperation between the two groups. In particular, the video (3:30), resolved entirely thanks to the digital modelling, shows an original visual and communicative approach. It starts highlighting the relationship between the building and the environment, the different functions, displayed with exploded isometric, the accessibility system. Then, describing the project, a particular camera movement alternating the acceleration and stop-image is used, combined with special representation techniques that change from the conceptual, in gray scale with a few spots of primary colours, secondary animations of people, vehicles, videos, up to static photorealistic images delicately rendered.

Opposed to the essentiality carried out in the previous case study, the imaginative language, rich in contaminations between real and virtual can be found in the next case.

The animation for the presentation of the HOK Sport Olympic Stadium (2007), to be built for the

Olympics and Paralympics in London, was created by the filmmakers of Squint/Opera.

The film is produced through hybridization of materials and languages, real footage and photographs with digital artefacts; the animation of three-dimensional model is reduced to a minimum in favour of applying dynamic post-production tools to the static views.

A short presentation, which simulates a communication of television news, introduces the project, firmly framed in the atmosphere of London through the city landmarks (the City Hall, the Tower Bridge and the Battersea Power Station) progressively invaded by the flags of the Olympic competition. A child spectator from the beginning to the end of the event takes the viewer into the discovery of the project elements. These are realized through geometric models of roofs, services, seating and structural system that immediately become, through animation, in other objects related to the fantasies of the child: the colourful ellipsoidal shapes of the services become flying ships, the seats in the form of gulls arrive from above, the three-dimensional trusses move to the place of foundation as they were snakes, while in the background there is the real city. Finally, the elements reassembled and made static, assume again their geometric appearance related to the environment through a model illustrating the overall functions and accessibility. A sequence in

Figure 6. HOK Sport Olympic Stadium, London

Source: Movie by Squint/Opera (4:52), 2007

Figure 7. AllDesign, Great Beijing Theatre and Masterplan, Langfang

Source: Movie by AllDesign (2:44), 2010

which the realistic render of the three-dimensional model is set in motion through secondary animations of public, athletes, giant screens and actions of zoom, scroll, rotate, concludes the movie.

Among the current trends of the animation for the design representation, as seen in the description of the emblematic case studies, the minimalist choices consisting in conceptual views, in animations that refer to the simple movements indicated above by Manovich, in attention to the concept communication and the artefact constructability, can be affirmed to prevail.

Moreover, the video production within the same study of architecture is witnessed in many cases, facilitated by the most common software for modelling, rendering and post-production.

Differently from the most of the architects group websites, that led by Will Alsop, which name is AllDesign, shows his projects by movies besides static renders. These movies at first realized by Squint/Opera or Virtual Artworks are nowadays produced inside the studio.

The choice of attributing a central role to the movies in the communication strategy of the architect's team, in tune with the graphic style of his website, stimulates more involvement by the viewers.

The video for presenting the project for the complex of three theatres in Langfang, near Beijing, in 2010, was produced by the same AllDesign

studio that, in its website, claims to create movies since the best way to express their own ideas is telling a story.

The short video (2:44) introduces the narration with a recall to some images of the traditional Chinese landscape: vegetation of bamboo, flowering cherry-trees, canoes on the lakes and, finally, the wild boar, of which metamorphosis, described as the initial concept, gives shape to the project. The complex aims to fit into the natural environment with the creation of a park with ship canals and walkways leading to theatres and shady spots designed as a meeting place. The architectures, displayed in conceptual clay-render, on which the connecting blue ring raises, are part of the system of the green. Animations, fly-through, static rendering zoom and scroll and simulations of the growth of the artefacts and the green, combined with the apparition of evocative images (musical notes that come out of the buildings and moulds of traditional theatre masks) constitute the sequence.

The video for the architectural competition in 2012 for Copenhagen Arena, presented by C.F. Møllers, shows a multifunctional complex intended for sports and concerts, without losing its human scale, becoming a landmark, a building element of the landscape and an attractive element of activity. The animation (3:54), presumably produced by the same architectural studio, initially presents, in a bird eye view, the structural

Figure 8. C.F. Møllers, Suggestion to Copenhagen Arena

Source: Movie by C.F. Møllers (3:54), 2012

technologic and constructive elements and the building phases of the stadium, set within a context geometrically modelled and clay-rendered. When the video camera is lowered to the human level, its recurrent motion is the rotation around the conceptual model. The following still image is characterized by the representation as a realistic static rendering to which actions of scroll up or zoom out are slowly applied.

SOLUTIONS AND RECOMMENDATIONS

In summary, methods, techniques and figurative choices in the ambit of the architectural animation, highlighted by the selection of case studies proposed above, can be synthesized as follows.

One or more geometric models of a design having an appropriate degree of detail in relation to the positions from which they are filmed, which are based on figurative convention for the architectural representation: dynamic bird eye views emphasize relationships between the building and the existing environment, while those at human eye height give a preview of the perceptual impact of the future settlements; orthogonal views of horizontal and vertical sections illustrate the space distribution and the functional aspects.

The figurative decisions reconcile the design poetics of the architects on the one hand and the narrative styles of the producers on the other, fluctuating between conceptual and hyper-realistic styles.

The camera movement is not generally at a constant speed, accelerating and slowing, sometimes moving rapidly on tracks to get close to the action or following the pace of an avatar who guides the spectator in the discovery of the place, while secondary animations, of men and vehicles in movement, monitor which projects films and fountains and fireworks overlap the primary animation or a still image of it.

The time dimension, introduced by the movement of the camera, is frequently overlapped by

the representation of the natural flow of time, with animations which start in the daylight and end at the night, thereby facilitating the entire daily life cycle of the object.

Animated projections are always accompanied by sounds. They can range from background music which captures the attention and helps focus the observers' attention on the noises which enliven scenes evoking feelings of empathy and the recognition of places.

Finally different video production techniques can be observed, finding their place of convergence in the digital world (Ciotti & Roncaglia, 2000): the composition of different two and three dimensional views of digital models with photographs and texts using the established technique of stop-motion combined with movement options such as fades, zooms, pans and scene changes which are practiced today using dynamic postproduction software; the modelling of building designs in their existing context, also modelled, but often in a summary manner and the formation of a long route along which a series of rendered views are created; the modelling of building designs inserted dynamically in a film of the environment using camera-tracking techniques.

FUTURE RESEARCH DIRECTIONS

Architectural videos, today with a greater presence, sometimes are accompanied, above all in the web-sites, by the extremely recent and occasional introduction of 360° panoramic views, which offer a modest degree of interaction, and by virtual views, which, on the contrary, offer a certain number of scenarios that can be freely selected and navigated by visitors.

CONCLUSION

The rapid development of digital technologies makes foreseeable a greater interactivity between observer and digitally simulated space, with the

ability not only to freely explore the project, but also to modify it in real time. The author believes that in the same time the research on languages should advance, with the aim of increasing the wealth of knowledge provided by the animation, not only with respect to the users, but also to the designers themselves who could find another effective verification tool and project control thanks to it.

KEY TERMS AND DEFINITIONS

3D Modelling: In 3D computer graphics, 3D modelling is the process of developing a mathematical representation of any three-dimensional surface of object via specialized software. The product is called a 3D model.

Animation: Animation is the process of creating a continuous motion and shape change illusion by means of the rapid display of a sequence of static images that minimally differ from each other. In the architectural representations, animation can be the creation of a path inside and outside of buildings, or the putting in motion of static elements.

Compositing: Compositing is the combining of visual elements from separate sources into single images, often to create the illusion that all those elements are parts of the same scene.

Montage: Montage is a technique which uses rapid editing, special effects and music to present compressed narrative information.

Post-Production: Post-production is part of the process of filmmaking, video production and rendering, which consists in a series of editing and optimization of the product, subsequent to the camera shot or the animated sequence creation.

Rendering: Rendering is a image generated by a computer using three-dimensional modeling software, after applying materials and lights and setting a perspective view.

Secondary Animations: In architectural movies, the secondary animations consist of motions of people, vehicles, videos which overlap the animation created by the video camera movement.

Literature Review of Augmented Reality Application in the Architecture, Engineering, and Construction Industry With Relation to Building Information

INTRODUCTION

Productivity rate in construction industry shows a general pattern of decline in comparison to other industries. This issue influences on performance and efficiency of construction projects by adding unnecessary costs, time, materials, and manpower waste Alwi, Hampson et al. (2002). In dealing with this issue, it is necessary to apply proactive approaches rather than reactive ones through using new method and processes in the construction industry. During the last decade, Information and communication technologies (ICT) have been advanced significantly where the application of these technologies could improve the construction industry efficiency to some level (Park & Kim 2012). However, in order to fulfill this task in a larger scale, new methods and processes are required to develop and analyzed. This paper presents a conceptual framework to enhance construction industry efficiency via a comprehensive and proactive mechanism of Augmented Reality (AR) and Building Information Modeling (BIM) linkage. To fulfill this objective, the study begins with an extensive and critical review on AR and BIM separately in order to investigate the efficiency of each technique in the construction industry. Then the study proposes a conceptual framework of AR and BIM combination by investigating this collaboration in the enhancement of construction industry procedure.

BACKGROUND

Augmented Reality (AR) provides the means for intuitive knowledge presentation by enhancing the perceiver's situational awareness and cognitive perception of the real world. Through AR approach, virtual objects can be registered in relation to real objects where these objects can be seen in the same position and orientation of other real objects of the scene, as perceived by the user (Wang et al. 2004). In addition the real objects can be tracked and their 3D shape can be reconstructed from pictures (Azuma 1997).

AR has introduced as a technology which allows the user to see, hear, touch, smell and taste things that others cannot (Van Krevelen and Poelman 2010). It is a technology to perceive elements and objects within real world experience in a complete computational environment. It applies creatures and structures that could be used in daily activities unconsciously through interaction with others such as enabling mechanics to see instructions for repairing an unknown piece of equipment, surgeons to see ultrasound scans of organs while performing surgery on them, fire fighters to see building layouts to avoid invisible hazards and people to read reviews for each restaurant on their way (Feiner 2002). (Wang and Dunston 2007) describes AR as a tool allowing users to work with real world environment while visually re-

DOI: 10.4018/978-1-5225-2255-3.ch085

ceiving displays of additional computer-generated information about the item by superimposition of additional information onto the real world scene. This approach enhances the user's perception of the real environment by showing information that cannot be sensed unaided.

It is expected that in the near future, an increase in the use of AR applications will occur due to the advancement of hardware and software. (McKibben and Furlonger 2009) predict that by the end of 2014 approximately 30% of workers will use some form of AR capability and after a long period of technological development and refinement, the implementation of AR applications for the general public will reach its peak. In addition, the commercial market shows a same trend by promising examples such as Project Glass as an R&D program by Google (Goldman 2012) to develop an AR head-mounted display (HMD) for enabling users to experience a truly immersive digital life. ABI Research (Hyers 2006) predicts that by the end of 2014 the revenue from the AR mobile market will reach \$350 M and Juniper Research (Holden 2005) predicts that the market for AR services will reach \$732 M at the same time. It is widely believed that AR technologies are maturing and that within the coming years they will be broadly adopted by industry.

Estimations show that at least 5% of total building construction costs are due to occurrence of problems in the early design process, causing insufficiency, inconsistency and omission of design-related information towards construction phase (Hwang, Thomas et al. 2009). Construction worksite layout planning relies mainly on 2D paper media where the worksite planners sketch the future layout adjacent to their real environment. This traditional approach is ineffective and prone to error because only experienced and well-trained planners are able to generate the effective layout design with paper sketch (Wang and Dunston 2007). In the architecture, engineering and construction industry (AEC), gaps between planned solutions and practical implementations, poor communications between project participants

and inefficient scheduling are the main issues for the lack of sufficient information/communication technology (ICT) support and innovative business procedures (Chi, Kang et al. 2013). (Froese 2005) has categorized trends in construction ICT into three categories. The first category is stand-alone tools to assist specific work tasks such as CAD, structural analysis and estimating programs. The second category includes communication and on-line information sharing tools through worldwide web document management system. Finally the third category includes the potential for integrating first and second category as a cohesive model through Building Information Modeling (BIM) (Froese 2010) where project teams come together to produce comprehensive and virtual prototypes of all aspects of the construction project as the central activity.

With the progress of ICT use in the AEC industry, higher quality visualization platforms are necessary for the efficient use of shared information among involved teams. Available research studies show the attempts of construction activities simulation with feedback generation through visualizing construction information for easier understanding and data share among project participants (Kang, Anderson et al. 2007). However, this approach only enables the visualization of activities in the virtual environment without enough resemblance to the actual tasks in the real world. (Froese 2005) introduces AR approach for the generation of digital project information prior to construction with transfer onto construction site in a fully digital way where this process facilitates the comparison of the actual situation with the planned final appearance to identify the concerned items.

Building Information Modeling (BIM)

(Penttilä 2006) defines BIM as a set of interacting policies, processes and technologies that generates a methodology to manage the essential building design and project data into digital format throughout the building's life cycle. BIM creates an

interdependency environment between structural, architectural and mechanical services (Dossick and Neff 2009) with digital representation of the facility's physical and functional characters to provide a shared knowledge resource for client or user to use and maintain throughout the project's life cycle (Eastman, Jeong et al. 2009).

According to the studies by (Taylor and Bernstein 2009), BIM can incorporate parametric 3D, 4D and 5D modeling where 4D includes a time dimension and 5D contains time based cost model. In addition, studies by (Aouad, Lee et al. 2006) presents the expansion of BIM into nD environment in the recent developments of AEC industry by incorporation of engineering analysis and construction business functions during the lifecycle of a building. This expansion includes scheduling, cost analysis, quality control, accessibility, safety, maintenance, sustainability and energy simulation. However, despite the recent BIM developments in the AEC industry, it still requires further progress during construction phase, specifically in relation to the daily monitoring of work and management of involved teams.

Augmented Reality (AR)

Generally, the life cycle of construction project consists of five phases as a) project feasibility analysis; b) planning/design; c) construction; d) operation; e) disposal (Halpin and Woodhead) where each phase requires the creation of physical structures and elements to create visual information for understanding and communicating the complexity of projects with consideration of relation to existing structures or elements. With recent advances in computer interface design and hardware capability, the application of AR research prototypes and test platforms have fostered in the construction industry (Yang, Tsai et al. 2011). However, AR technologies itself are not advanced enough to be applied effectively in real AEC projects and there are two main issues in this regard and they must be addressed before AR technologies can become prevalent in the AEC industry. The first issue is the limitation of

available technologies to support AR approach and the second is to identify appropriate application areas for the use of AR in the construction projects. To clarify the issue, (Stanco, Battiato et al. 2011) studied the accurate alignment of virtual objects in a real world scene with regards to the user's orientation and position. Their research identified recent tracking technologies for indoor, prepared environments with accurate registration, but the lack of strong accuracies tracking techniques for outdoor environments due to the scale difference. (Yokokohji, Sugawara et al. 2000), demonstrated a system combining accelerometers and video tracking registration for analysis of indoors, but its' non-practicality for outdoor and unprepared environments.

In order to create an efficient application of AR in construction projects, it is necessary to identify the areas with the highest potential for better performance. (Balzani, Santopuoli et al. 2004), demonstrated the potential of AR as a visualization aid for underground structures and (Bruner 1966) discussed the benefits of AR for architectural assembly guidance, infrastructure field tasks, urban planning and design detailing.

Therefore, the analysis of current literature, suggests the feasibility of AR technologies to increase the likelihood of success in the AEC industry with the consideration of its suitability validation in each case.

FURTHER RESEARCH DIRECTIONS

Integration of Augmented Reality into AEC Industry

Research by (Chi, Kang et al. 2013) presents the four rapidly developing technologies in the application of AR approach to integrate the virtual world with the real world as a) Cloud computing environment; b) localization; c) portable/mobile devices and d) natural user interface (Table 1). The application of these technologies plays a significant role in the integration of AR into the AEC industry.

Table 1. Architecture of AR application in 4 phases adapted from “research trends and opportunities of augmented reality applications in aec”

Architecture of AR Application			
Data Phase	Computing Phase	Tangible Phase	Presentation Phase
Cloud Computing Environment	Localization Technologies	Portable Devices	Natural User Interface
BIM	GPS	Cheap	Gesture
Internet	RFID	Light	Motion Capture
	Barcode	Wearable	

Source: (Chi, Kang et al. 2013)

Cloud Computing Environment

Cloud computing has become a powerful technology with the progress in the Internet data processing speed where it has the potential to extend the use of AR and BIM applications in the AEC industry. Research by (Jardim-Goncalves and Grilo 2010) emphasizes the shifts of CloudBIM approach from stand-alone static applications to dynamic shared environment with dynamic tasks allocation and access via a network. Internet operation in real time and cloud-based computer devices helps to make the required information more accessible to the users by enhancing the AR experience with the possibility of virtual information update or change by the cloud side. Therefore, similar to the use of web browser, the involved parties can use the AR as the front-end to explore the virtual information with extra access to more variable and meaningful information in the field. According to (Kamat, Martinez et al. 2010), it can benefit construction field tasks such as schedule monitoring and building inspection where they require huge amounts of dynamic information.

Localization Technologies

(Chi, Kang et al. 2013) expect the localization technologies influence in the future development of AR applications and they introduce it as part of the core functionality of AR technology with its necessity in identifying the posture of subjects. However, the accuracy of the localization method introduces the limitations of AR applications in

superimposing virtual information into the real world. To solve this issue, a research by (Zhang and Hammad 2012) discusses the development of global positioning system (GPS) and outdoor localization technologies such as radiofrequency identification (RFID), ultra-wide band (UWB) and barcoding where all combine multiple sensors to provide the accurate functionality. Despite the current developments, still all available localization approaches are limited by environmental complexity, signal quality, ranges of sensors and uncertainty where it makes it difficult for developers to maintain the accuracy level of AR and to promote the use of AR applications before improving its accuracy.

Portable and Mobile Devices

The size, weight, performance, and cost of hardware directly influence AR applications where the portability of AR depends on the level of mobility a hardware device can provide. This issue requires AR systems focus on portability and providing the ability to maneuver at outdoor environments. Research by (Yang, Tsai et al. 2011) highlights the need for all AR devices to be stable and capable of surviving in the variable environments. Until this capability is achieved, new AR applications will not become available.

Natural User Interface

(Yeh, Tsai et al. 2012) define natural user interface as intuitive control mechanism that imitate human

behaviors and gestures with consideration of an increasing number of AR applications utilizing gesture controls such as Sixth-Sense as a wearable gestural interface that augments the physical world with digital information and enables the users to interact with the digital information using natural hand gestures. However, their research clarifies the dependency of AR application not only on its stability but also on the quality of the control interface. Future research requires the control interface to be more intuitive and more stable with fewer sensing limitations where it will reduce the risk of operating AR devices in dynamic environments such as construction sites.

Combination of Augmented Reality and Building Information Modeling

BIM related research has predominantly focused on enhancing communication and collaboration between stakeholders through the use of 3D modeling and 4D simulation throughout a project's life cycle (Love, Edwards et al. 2011) where BIM is utilized simply as a representation and simulation tool. The issues dealing with large quantities of data and their accessibility have hindered the use of BIM being effectively implemented on the construction site and even the issues regarding the application of BIM from design to real-time on-site construction have not explored thoroughly yet. However, the contained information within BIM should be used during construction to ensure that activities and tasks are completed on time according to schedule and to ensure the desired quality and safety standards are met (Construction 2008).

While BIM provides static and pre-defined data and information, AR can be integrated with BIM to enable the physical context of construction activities visualization with real-time monitoring of tasks. The integration of BIM with AR can provide a platform for a site management team and subcontractors to effectively interact and utilize the BIM model contained data (Hou and Wang 2011). This translates to a major opportu-

nity presented by the use of BIM+AR technique as the ability to work at real-scale in all phases. Involved people in the building process, such as clients or prospective buyers, often have difficulties understanding and translating 2D CAD architectural representations into real 3D spatial models where they basically need to build up their individual mental models to understand the project (Donath, Beetz et al. 2001). There is also a need for a powerful and proper visualization approach to supply information to the onsite workers. BIM can make the interdependencies between work tasks more explicit with making the existing complexity more visible and manageable onsite. It can be a proactive approach where the potential negative impacts of any action can be identified earlier and mitigated avoided easily. Spatial collision analysis between trades by 3D modeling systems such as CATIA or Navisworks is an example of this approach (Wang and Love 2012). However, during the actual construction process, there is a possibility of collisions occurrence due to the change of building elements, site facilities and the movement of construction machinery. Therefore, it is challenging to introduce the onsite real-time dynamic collision detection approach to include the variations of construction sequence and schedule. Addition of AR to BIM enables real-scale representations of the existing situation to be communicated and augmented by further information where misunderstandings between planner, client and involved parties can be better avoided with savings on additional cost measures and time-delays (Donath, Beetz et al. 2001).

Therefore, BIM+AR can be proposed as the fourth era of construction IT where prior to construction, the generated digital project information can be brought onto construction site with capability of being processed in a fully digital way. Simultaneously, the site crews will have the capability of accessing the information associated with the concerned construction component or entity in a fully digital approach (Froese 2005).

Figure 1.

Framework of Building Information Modeling and Augmented Reality Integration

(Wang, Love et al. 2013) define AR as an information aggregator to collect and consolidate information from BIM model with sensing and tracking technologies such as barcode, RFID, and GPS to identify, track and monitor individual resources. The tracking devices are mobile and ideal for onsite use to integrate BIM and AR where tags are attached to elemental components and the progress is monitored by identifying the details about the specific properties such as date, number, and text lists. Since the tags are recorded with predefined activities with the requirement of constructing a specific component and given capability to the site operator to record comments of each activity, it can be a direct link between the BIM model and AR database where both containing drawings and documents linked to a specific component and element database.

The Generation-Communication-Evaluation and Decision making (GCED) cycle was propagated by (Arayici, Coates et al. 2011) as referring to the typical onsite decision making process. In this approach a potential solution is generated before its being communicated and being aware of the potential solution, its evaluation can commence based on a set of pre-defined criteria and then decision can be made. As an example, the architects who design the building envelope interact with

engineers developing the steel structures and when architects and engineers engage in discussions related to complex geometrical relationships such as facades, the GCED cycle commences (Figure 1). In the conventional approach, physical mock-ups are created considering their time-use and inaccuracy where many features and properties are lost. Another method is creation of computer-generated models prior to discussions with the consideration of their ongoing insufficiency for evaluation and collaboration purposes. Integration of BIM with AR enables the visualization of buildings 3D models with their detailed features where their properties can be visualized directly onsite to support AEC team in their communication and dynamic generation of alternative site solutions.

Similarly, in second study by (Froese 2010, Arayici, Coates et al. 2011), the framework for integration of BIM and AR is defined in four steps. First, the design and planning of construction process starts with the creation of digital prototypes in BIM model where it contains both geometric and non-geometric information. Second, the BIM model is used as the reference guide to organize the production process. Third, each involved party carries out their role according to the drawing information from the same AR based BIM model where the models are used to support effective interaction and communication. Fourth, the work results are used to update the same BIM model through the function of AR annotation and commenting.

DISCUSSION

(Behzadan, Timm et al. 2008) discuss the recent developments in mobile processing units, camera quality and tracking technology where they enable AR applications to be implemented in different environments. Available mobile augmented information has various applications at the construction site including construction work planning, verification, training and safety, communication and marketing prior to construction work. Seamless interaction cycle between the real world and digital building information model developed by (Hakkarainen, Woodward et al. 2009) identifies the camera location in order to implement mobile location based visual feedback from the construction site to the BIM system with full awareness of the user's location in time and space.

(Irizarry, Gheisari et al. 2012) developed a low-cost mobile AR based tool for facility managers called InfoSPOT as a mobile AR method for accessing building information through a situation awareness approach where a real world example of a BIM was applied to test its development. The authors discovered the challenging problem of the BIM being inconsistent with the built environment and in order to solve this issue, they optimized the geometry to reduce the BIM complexity in displaying on a mobile device. Their statistical analysis indicated a generally positive response for this inexpensive solution and suggested it will assist facility managers in their routine tasks where the real-time views of space can be supplemented with vital information. They concluded that AR solutions can be easily setup and the costly hardware installations were unnecessary for a successful AR application.

(Jiao, Zhang et al. 2012) presented an AR framework integrated with a BIM and cloud computing technologies where they utilized Web3D technology to display virtual objects and resulting solution from integration with an as-built BIM model. The authors suggested the framework capability of being used in real data application where it can support collaboration in a

more natural and effective way with the power of cloud services. They conducted a test case with an actual construction project and their results demonstrated the usability of the proposed framework to source virtual objects from BIM and to support collaboration. They concluded that the extension of the framework as a daily tool for construction applications require further research in the future.

(Park, Lee et al. 2012) proposed using AR for the management of defects during construction where they made an investigation in the construction industry for identifying current issues and requirements of defect management practices. Their studies presented a conceptual system framework integrating AR with BIM model for construction defect management. Based on the laboratory tests, the authors concluded that the BIM+AR system will enable managers to efficiently inspect and control their worker's job performance with allowing workers to readily confirm their works in real-time.

(Kandil, Hastak et al. 2014) proposed the integration of BIM model with AR for ductwork installation and clash detection involved in erecting the HVAC system. Even though the conflicts and clash detection can be largely identified in BIM model during design, design changes and errors or poor installation may lead to conflicts arising onsite. Using integrated AR allows a site manager to address the potential for conflicts onsite by retrieving and visualizing all the concerned properties and details in the BIM model where it can improve speed, safety and accuracy as well as reducing the cost.

CONCLUSION

Despite the limitations of building information modeling (BIM) to the design phase throughout the project lifecycle, it has started to be implemented in the construction industry in the recent years. In the meantime, augmented reality (AR) as a new and emerging technology in the construction industry deems to be a key enabler to address

the current shortcomings of using BIM onsite throughout the construction process. While BIM can be used to improve the efficiency and effectiveness of design coordination, it is unable to take into account the inherent uncertainty associated with design changes and rework happens during construction and particularly in complex projects. With the rapid development and adoption of AR applications, there are numerous opportunities to integrate BIM and AR in order to visualize the information about as-built, as-planned and future progress.

In this paper, the current trends in the development of AR applications were identified and a series of examples were presented in the application of AR technologies in the AEC industry by describing how BIM+AR can be used for reasoning the interdependences of tasks, project progress monitoring, digital to physical relations, material flow tracking and visualizing design during production. However, more research and case studies are required in the future to empirically examine the proposed integrated framework in obtaining the potential productivity and performance improvements in the construction industry.

KEY TERMS AND DEFINITIONS

Augmented Reality: A live direct or indirect view of a physical and real-world environment

where the elements are augmented by computer-generated input such as sound, video, graphics, etc.

AEC: Stands for architectural, engineering and construction field.

Building Information Modeling (BIM): A process where it involves the generation and management of digital representations of physical and functional characteristics of items or places.

Literature Review: A text of a scholarly paper including the current knowledge and findings alongside the theoretical and methodological contributions to a particular topic.

INTRODUCTION

Mental health providers cannot ignore the importance of utilizing technology in this era of the “Internet of Things.” This chapter reaffirms the need for mental health providers and software developers to work in concert with each other when developing technology for mental health. We also articulate the importance of the patient and the patient’s role in connecting technology into the equation.

BACKGROUND

The Problem

Marks and Bowers (2014) developed a taxonomy that allowed mental health providers to understand how technology can benefit patients as well as direct the provider to the proper platform depending on the aspect of the patient’s mental health requirements. A taxonomy was developed that included classifications of disorders with specific disorders from the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (*DSM-5*), delivery platform i.e., mobile device, personal computer, and video game console, and the four classifications of mental health services (e.g., Training, Therapy, Assessment, and Prevention). This taxonomy guided developers to focus

on building mental health technology (mHealth) that revolve around a particular sector. Further, the taxonomy capitalized on the similarities between providers and developers in achieving the end-goal of repeated and continued use of their respective product (therapeutic services and software). However, the previous taxonomy did not account for the different motivational strategies employed to reach the end-goal; in the design and development of mHealth providers and developers focus on two different factors. Providers focus on delivering evidenced-based treatments driven by underlying mechanisms of action (MOA); whereas, developers focus on delivering usable and entertaining technology. Compounding this disparate approach between providers and developers is the failure to take into account the patient perspective. The present chapter presents a revised taxonomy that represents the integration of MOA, usability and entertainment, engagement to create gamified technology for the purpose of increasing, repeated and continued engagement with the technology, by the end-user. The taxonomy has been revised to reflect the change of including the end-user and integration of gamification. Additional changes have been made to the taxonomy to better represent this new focus. These include changes to the component of Training, which is now called Psychoeducation; Assessment, which has been removed from the taxonomy because the focus of technology for assessment is not for the

DOI: 10.4018/978-1-5225-2255-3.ch086

end-user. All changes have been made in an effort to better synthesize the newly added information afforded by considering the end-user, in pursuit of creating repeated and continuous engagement with mHealth.

To better understand the disparate approaches between providers and developers and how the end-user will be incorporated, an explanation of each motivational target of the triad is warranted.

Provider

The mental health provider's goal is clear: it is to help a patient improve upon a targeted domain that is interfering with the patient's quality of life. Mental health providers agree that motivation is a key component to attendance and participation in treatment. Without motivation, therapeutic processes cannot take place nor be effective. At each step of the therapeutic process the mental health provider guides the patient through the therapeutic process, and works with the patient to determine the pace of progression to end goals. It is through clinical experience that is informed by research, that the provider makes these crucial decisions.

The therapeutic process involves the general components of 1) establishing a therapeutic alliance, 2) establishing what is the patient's commitment to change, conducting a behavioral analysis, coordinating treatment objectives, 3) executing treatment and maintaining motivation, monitoring progress, and 4) planning for treatment termination by generalizing skills (Rosenbaum & Horowitz, 1983). These steps create a tailored versus standardized treatment structure, and encourages the patient to be an active participant in the progression toward change (Kanfer & Grimm, 1980). It creates a therapeutic alliance between the mental health provider and the patient. The therapeutic alliance refers to the patient's experience as to the mental health provider's empathy; it refers to the patient's belief as to the provider's credibility as an expert; it refers to the patient's perceived rapport with the provider; it refers to the patient's perception that he or she is receiving the help needed from

the provider; it is the patient's perspective that the provider is engaged; it refers to the patient's perception that the treatment is a process working toward specified goals (Elvins & Green, 2008). This therapeutic alliance, while not a specific strategy for motivating patients, encompasses all domains of influencing motivation to adhere to treatment (Barrett, Chua, Crits-Christoph, Gibbons, & Thompson, 2008; Bordin, 1994). The best form of treatment requires practitioners to focus on evidence that supports effective intervention using evidence-based treatments. Evidence-based treatment involves the integration of best available research, clinical expertise, and consideration of individual patient characteristics (Anderson, 2006). In essence, each treatment has an underlying MOA. Considering that mental health providers should be delivering evidence-based treatment in a traditional face-to-face format, providers should continue to provide the best possible treatment regardless of the platform. The focus of the mental health provider is on mHealth's ability to support treatment rationale and adherence to clinical practice.

Developer

Adams (2014) describes the developer's job as brainstorming designs, creating meaning, distinguishing content, and testing the technology. Adams organizes the developer's software designing job into a three-part system:

1. **Concept Stage:** Deciding the kind of technology to develop.
2. **Elaboration Stage:** Creating and developing the software, then conducting usability testing.
3. **Tuning Stage:** Preparing the software for release, including fixing errors in code.

The second and third steps are particularly important because developers desire for users to spend time playing the software and do so on a repeated basis, which, as an aside, is consistent

with the desires of mental health providers (Von Ahn & Dabbish, 2008). In fact, there is evidence noting that evaluating usability is crucial in motivating people to engage in the use of mHealth technology. Poor usability and user experience has demonstrated to de-motivate people from using the technology (Spillers & Asimakopoulos, 2014). When issues of usability are resolved, elements that facilitate great technology can be implemented.

Gamification, while not a specific strategy for motivating players, summarizes the integration of elements that compose great games. Successful mHealth games have goals, rewards that people are excited to obtain and, thus, play in order to achieve. Developers elicit excitement by integrating elements that capture attention, relevance, confidence, and satisfaction (Keller, 1983; Paras, 2005). The excitement is palpable and fosters motivation to continue playing. Players work hard to advance in game play by completing levels, collect badges, earn coins, and receive points, in other words, positive reinforcement. The aforementioned rewards are direct reflections of the link between the player's effort and achievement (Malone, 1982). The visual representation of effort and outcome is highly rooted in the competitive nature of a player, which when combined synchronizes and increases the desire to continue playing (Vorderer, Hartmann, & Klimmt, 2003).

This visual representation is a form of feedback, which leans on our innate desire for immediate feedback regarding performance. This desire for immediate feedback is present regardless of context, which in this case, happens to be within a game environment (Ciampa, 2014). While typically viewed as positive, immediate feedback received within the game environment can serve as a potential source of frustration - frustration stemming from game elements being too demanding (Tauer & Harackiewicz, 1999).

Establishing an equilibrium of a game's goals between simplicity, which can be boring, and difficulty, which can be aggravating is essential when considering motivational target of repeated, continuous, use (Malone & Lepper, 1987). This

balance is imperative to keep the player interested and motivated in advancing towards the end goal (Richards & Caldwell, 2015). The balance starts with developing a game progression embedded with appropriate challenges and sufficient rewards (Richards & Caldwell, 2015). The in-game rewards of advancing thru the game and earning the aforementioned reinforcement is intrinsically motivating as it captures the notion of progress (Klosowski, 2014).

Another aspect that motivates individuals to advance towards the end goal is the incorporation of narratives, or stories (McDaniel, Fiore, & Nicholson, 2010). Strong storytelling stimulates the users draw to the game, in turn, providing motivation to play. The strength of the story is enhanced when relatable avatars are leveraged. Relatable avatars provide players the feeling of personal connection to the game (Doyle, 2004). The opportunity to customize avatars deepens the player's personal connection to the game leading to enjoyment, and therefore, increased time spent within the game environment (Doyle, 2004; Schmierbach, Limperos, & Woolley, 2012).

The emphasis of the developers' motivational targets, however, is on whether or not the technology is usable and entertaining for the target audience, not that it will actually be used. Just because a technology is *usable* and *entertaining* by definition, does not ensure that the technology serves its' purpose in regards to the providers' MOA. This implies that there is a third variable in the equation, and that is the end-user, patient.

End-User, Patient

End-users validate technology. The End-user must be taken into account at the design phase in order to ensure usability that fosters prolonged and repeated use and engagement. Specifically, the inclusion of an entertaining, usable, mechanism of action driven mHealth will not predict actual use of said technology. Only 35% of adults who own phones have downloaded at least one app, but only two-thirds of those actually use these

apps (Purcell, 2011). A mental health technology simply for the sake of creation is not sufficient; no matter the appeal of health technology, it will not be used by the patient unless (i) it helps address with her or his specific problem and (ii) avoids technical failures, i.e., crashes, freezes, error messages (Perez, 2013; Scher, 2013). Perez (2013) demonstrated that only 16% of people would try to use an app more than twice if it fails.

In addition, mHealth design and functionality needs to provide flexibility by taking into account a patient's motivation to use the technology. Motivation to engage with the technology is rooted in the need to reduce symptoms of psychopathology, willingness to seek help, and improve quality of life (Wilson, 2007).

Mental health technology cannot consider each individual when designing technology. That is, symptoms that the technology is designed to mitigate may not line up perfectly with what the patient experiences. Yee (2006) hypothesized and defined three end-user, player, and motivational components as follows.

1. **Achievement:** A Player yearns to make progress within the game, which includes gaining power, wealth, and knowledge of the rules to "better" her or his character, avatar, as well as the inclination to compete against others in the game.
2. **Social:** A Player desires to form relationships and help others in the game, and enjoy being part of a group.
3. **Immersion:** A Player wishes to know what others players do not know and enjoys being able to customize her or his own story and character in the game.

The challenge, therefore, is integrating the benefits of face-to-face therapy into a game construct for mental health in order for the application of the Triad to the taxonomy to be effective.

APPLICATION TO THE TAXONOMY

Good user engagement offers insights into development of more effective implementation of MOA and incorporation of usability and entertainment. As illustrated, each component of the Triad contributes unique motivational targets. Similarly, each component of the taxonomy is different. In psychoeducation, the goal is to gain knowledge and apply that knowledge to the world outside. In therapy, the goal is to deliver a type of treatment that may address and help the patient cope with impairments to activities of daily living. Finally, in prevention, the main goal is preventing individuals (regardless of their risk level) from developing a disorder (Marks & Bowers, 2014). The challenge becomes creating a balance amongst each component to satisfy the MOA, entertainment, and engagement needs of each entity. The following recommendations about gamification guided by the motivational targets of provider, developer, and end-user.

Psychoeducation

Mini-Games

The goal of psychoeducation is to gain and apply knowledge to novel environments. Mini-games can serve as the mechanism for testing knowledge and assessing knowledge transfer. Mini-games are small games, play lasts under an hour, embody one learning goal, easy to learn, and difficult to master. Mini-games can be employed within several contexts and are best suited towards acquisition of conceptual and procedural knowledge (Smith & Sanchez, 2010).

Mini-games provide the opportunity for fun and engagement while simultaneously accomplishing the goal of providing the user with psychoeducation. New information is processed as stimuli, which is encoded during gameplay interaction.

In order to complete the game, players are required to memorize content and be able to recall for completion of the game (Smith & Sanchez, 2010). The advantages of mini-games are two-fold: one, in an environment where the provider is not able to directly observe the user's understanding, mini-games allow for the quantitative assessment of the users understanding; two, understanding, engagement is imperative in order for the user to gain the conveyed knowledge and retain the newly learned cognitive skills (Andrews, Joyce, & Bowers, 2010).

Therapy

Narratives, Avatars, and Alternate Reality Games

Narratives are powerful tools that embed learning content within the game to create a coherent story that motivates the user to continue their engagement in the game (McDaniel, Fiore, & Nicholson, 2010). In other words, narratives can be used for improving immersion by drawing the player into the world of the game. One type of narrative congruent with the face-to-face therapy format is the interactive story archetype. An interactive story is an experience in which the simulated world responds to the player's movements, decisions, and actions within the game-space (Bates, 1992; McDaniel, Fiore, & Nicholson, 2010; Thue, Bulitko, Spetch, & Wasylishen, 2007). The parallels between face-to-face therapy and the interactive story are seen by the emphasis that the player rather than that of the game structure dictates movements, decisions, and actions. The game structure is synonymous with the therapist, who provides the content and environment and the player is synonymous with the patient, who dictates the simulated world's response. This structure can assist with the creation of a therapeutic alliance between the user and the mHealth technology.

Further strengthening the therapeutic alliance, avatars should be considered during development of the interactive narrative. By placing empathic

characters that are, perceived to instill hope; perceived to be competent; and perceived to be committed, creates motivation for continued play. One example of translating the perception of commitment to the novel environment is the utilization of "push-notifications." Outside of the virtual environment, Avatars can be programmed to send "push-notifications" direct to the users cell-phone. Translating the narrative and the avatars presence from the virtual environment, to interacting with the user outside of the platform is reminiscent of alternate reality games. Alternate reality games (ARG) are a narrative that extends to the players real world (Johnston, Sheldon, & Massey, 2010).

The integration of an interactive story, empathic avatars, and ARG is an example of combining the motivational targets of the triad and addressing the problem of translation of gameplay to the generalizable, novel, everyday environment.

Prevention

Progression and Positive Reinforcement

Games are typically designed so that complexity and degree of difficulty increases as game-play progresses. Similar to games, users of mHealth technology will have a wide range of abilities and knowledge regarding the target of prevention. In a traditional face-to-face setting, a mental health provider will assess the current skill level, needs, and targets for improvement of the population targeted for prevention. A congruent assessment must take place within the game environment so that the difficulty of the game can be presented accordingly.

Increasing challenge can be designed by way of levels. Levels and degree of difficulty can be implemented by completing an earlier less challenging level, by increasing difficulty as time spent in game increases, or by an adaptive system. The adaptive system, as the name suggests, adapts by

Figure 1. Expanding the taxonomy of technology and mental health

Source: Marks & Bowers, 2015

adjusting degree of difficulty to the user based on their performance in game. The advantages of the adaptive system are evident considering that users become bored with games that are too easy or frustrated with games that are too challenging, which leads to discontinued play (Klosowski, 2014; Tauer & Harackiewicz, 1999). A user who has the skills and knowledge will be able to progress more quickly while another user will be provided the content in a more judicious manner.

This adaptive approach also lends well to the capturing and analyzing performance in real time. Two types of data can be generated using the adaptive approach. The first is what we would call performance “meta-data.” This data is derived from the capabilities embedded in smartphones and other software to track time spent engaging with content, length of time spent within a module/level, and the location of use. The performance meta-data can provide a mental health provider, as well as the user, with worthwhile information regarding level of engagement for the practice of skills. The performance meta-data can be synced

with in-game performance reinforcement (i.e., amount of time spent practicing skills and engaging in content results in collection of badges, coins, points).

FUTURE RESEARCH DIRECTIONS

The aforementioned suggestions are not mutually exclusive, rather the goal was to demonstrate how taxonomy for mHealth can be leveraged to synthesize information and best practices. Future research should look to understand the specific motivational targets that underlie each component of the taxonomy. Specific attention should be given to mental health technology that focuses on prevention. Primary prevention seeks to stop or stall the development of disorder. Primary prevention takes place prior to the expression of symptoms by intervening with all those who share characteristics that place them at risk for development of disorder (Cowen, 2000).

Figure 2. A Gamification, End-User incorporated taxonomy of technology and mental health

The very definition of primary prevention is that intervention takes place *prior* to the manifestation of symptoms. Whereas in training, therapy, and assessment, the patient has identified that there is interference in their quality of life that warrants attention. In prevention, there is a need to understand how to motivate people to use mHealth technology to promote resilience, and intervene prior to a problem developing. Targeting the motivational aspects unique to prevention would result in the increase of effectiveness of the primary prevention. The challenge is motivating a user to take the time to engage in technology that is perceived as a worthwhile investment of time.

Prevention technology is going to need to have more salient entertainment functions, but will also need to have strong therapeutic MOA. It is important, however, to understand that you cannot simply interpolate a game-like interface onto the MOA that is desired; rather, you must merge the MOA into the game (Von Ahn & Dabbish, 2008).

The original taxonomy, updated taxonomy, as well as the updated component of the taxonomy, has been included (see Figure 1, Figure 2, and Figure 3, respectively)

Figure 3. Updated component of the taxonomy of technology and mental health

CONCLUSION

The integration of provider, developer, and patient into the creation and development of mental health related technology will be crucial for ensuring success. Thus, in order ensure success, including increasing accessibility and utilization of mental health technology along with balancing mechanism of action, usability and entertainment, mental health providers and software developers must not forget the end-user, patient, in the creation and development of mHealth. Without a doubt, technology will be as relevant tomorrow as it is today, even more so, as technological advancements continue at an ever increasing pace and patient's become more reliant and dependent upon, and integrate technology into everyday life. As researchers and practitioners, the goal should be to create technology that will encourage repeated and continuous use of said technology, and not just technology acceptance in order to move the field forward toward the provision of low-cost, effective mental health services. Furthermore, each of the foregoing must ensure the continued evolution of such apps as new delivery platforms come to fruition. The Internet of Things is here to stay.

INTRODUCTION

Heart disease is one of the main causes of death globally. Some heart diseases may be diagnosed by measuring the pulmonary arterial pressure (PAP), which may be increased due to heart and pulmonary diseases. An increase in the pressure of the pulmonary artery could be an indication of pulmonary arterial hypertension, and may be defined as a mean PAP superior to 25 mmHg (Galie et al., 2009) and outside the 15-30 mmHg range for the systolic PAP (Edwards Lifesciences LLC, 2009).

For diagnostic purposes, most patients undergo an electrocardiogram (ECG), a chest X-ray, an echocardiogram, a computerized tomography scan of the chest, and a cardiac catheterization. The last one, the invasive arterial blood pressure (BP) monitoring, is considered the gold standard for BP assessment, providing accurate information, however it is also the most expensive (Chung, Chen, Alexander, & Cannesson, 2013). During a cardiac catheterization, a small flexible tube is inserted into a blood vessel in the arm or the groin, with a contrast dye that makes it possible to see under X-ray and obtain images of the heart structure and vessels. The catheter with a pressure sensor allows measurement of pressures in the vessels and heart chambers, which provide clues to a pulmonary hypertension diagnosis. Despite the catheterization procedure being performed

with the patient awake, and bring little or no pain, the patient may still feel pain in the blood vessel where the catheter is inserted. There is a mandatory rest time after the procedure. Also financial costs and risk discourage patients to undergo right heart catheterization procedure and from seeking potentially life-saving diagnosis and treatment of elevated PAP. Elevated PAP can be an indicator of pulmonary hypertension, a condition that may worsen over time, although treatments can relieve symptoms and give patients a better quality of life. The diagnostic we want to focus in pulmonary hypertension is the pulmonary arterial hypertension (PAH) that is a type of high BP that occurs in the right side of the heart and in the pulmonary arteries. PAH occurs when the pulmonary arteries thicken or grow rigid, this makes blood flow more difficult. The right side of the heart has to work harder to push blood through the arteries, and the arteries are not able to carry adequate blood to oxygenate in the lungs. It is difficult to continuously assess pulmonary arterial hypertension evolution, which motivates the search for accurate noninvasive PAP measurement devices.

BACKGROUND

A noninvasive estimation of the PAP is already in clinical use, the Doppler echocardiography; it uses ultrasound technology to measure PAP by

DOI: 10.4018/978-1-5225-2255-3.ch087

Figure 1. Phonocardiogram (PCG) representation with first (S1) and second (S2) heart sounds annotated

analyzing the speed of blood flowing through the heart. Doppler is widely used by cardiologists, it requires specific equipment, a specialized and trained doctor, and therefore it is difficult to be used for continuous monitoring, or in places without specialized healthcare professionals. Also some patients are not candidates for Doppler due to physiological constraints or poor signal-to-noise ratio: PAP cannot be estimated in 34 to 76% of patients with chronic obstructive pulmonary disease, 10 to 20% of patients with elevated PAP, and the most important in approximately half of patients with normal PAP (Xu, Durand, & Pibarot, 2003); also the Doppler estimations present an average error of 30% compared to right heart catheterization (Smith & Ventura, 2013).

Another method proposed for PAP noninvasive estimation is the heart sound analysis. Phonocardiography is a technique that generates a record of sounds produced by the contracting heart, resulting from valves and associated vessels vibration, the phonocardiogram (PCG), as we can see in Figure 1.

The sound is collected with a stethoscope over the main auscultations points on the chest; for the detection of pulmonary hypertension, usually the second heart sound exhibits an hyperphoresis of the pulmonary component, more audible over the pulmonary auscultation site (Young, 2001). Recent rebirth of the stethoscope, with electronic record of the PCG, has led to the search of automatic signal processing techniques to detect this clinical sign,

and few studies have addressed this issue in the literature (J Xu et al., 2002; Lim, Shin, Park, & Bae, 2013; Nigam & Priemer, 2004). Phonocardiography has been used to estimate PAP from noninvasively recorded heart sounds using models for how these sounds correlate with PAP. There are however several research questions that need to be answered in the PCG study, namely the robust segmentation of heart sounds, and modeling of the heart components that allow the extraction of relevant clinical information. It is a necessity to better understand the PCG and its relation with the PAP. To allow a better comprehension of the problem, the following sections provides a brief introduction to the anatomy, physiology, and the heart sound genesis.

HEART SOUND ANALISYS FOR HYPERTENSION DETECTION

Several studies have addressed the way information contained in the heart sound may be related to the arterial BPs at the heart output. This method has been studied with more emphasis on the detection of patients with PAH, considering the frequency, the amplitude, and split of the constituent components of the S2 - aortic (A2) and pulmonary (P2) - corresponding to the closure of the homonym heart valves (Nigam & Priemer, 2004; Jingping Xu, Durand, & Pibarot, 2001).

In order to estimate the BP it is important to separate the S2 components, meaning the aortic and pulmonary components, which has revealed to be a challenging task. In this section we intend to describe the main challenges for the second heart sound analysis, with emphasis on the PAH detection, since this is the most developed to the moment.

The first task in the analysis of the second heart sound is to detect the boundaries between the reference sounds. The concern here is that when the heart sound is registered several other sounds are mixed together, and the objective is to recover the heart sound components from that combined signal.

One of the most cited papers on this subject is the Liang et al., their algorithm segments the heart sound into four parts: the first heart sound, the systole, the second heart sound, and the diastole. The authors consider segmentation of the PCG the first and the most important step of analysis in automatic diagnosis of heart sounds. This algorithm first applies a low-pass filter with a cutoff frequency at 882Hz, to reduce noise outside the range of interest, and then converts to energy with a normalized average Shannon energy of the PCG signal. They compared different envelope methods and demonstrate that the Shannon entropy is the best to attenuate the effect of high amplitude noise that contaminates the envelope.

The peaks are detected based on the following criteria: one peak is always picked up; more than two neighbor peaks detected means the existence of split first or second heart sound, so the first peak is picked up in order to get the onset of each sound. To exclude peaks that do not correspond to any of the heart sounds, the following criteria are used: (1) when two peaks appear within 50 ms, which is the largest normal sound interval, and the energy of the first peak is not too small compared to that of the second one, the first peak is chosen, otherwise the second peak is selected; (2) when the interval between two adjacent peaks exceeds 50 ms, their energies are compared. If the energy of the first peak is larger than that of the

second one, and the last interval meets certain consistency of every second interval, they pick up the first one, otherwise the second one is picked.

To find which peaks are S1 and S2 the authors assume that the largest interval of a recording (within 20 seconds) is the diastolic period, and that the systolic period is relatively constant compared to the diastolic one. They decided to confine the duration of heart sound between 20 ms and 120 ms. The performance evaluation was made using 515 PCG signal segments recorded from 37 subjects, including normal and abnormal (Liang, Lukkarinen, & Hartimo, 1997).

There are more recent and complex studies of this problem like (Nieblas, Alonso, Conte, & Villarreal, 2013) that uses a matching pursuit algorithm achieving a detection rate between 96 to 97.5%, or (Papadaniil & Hadjileontiadis, 2014) that analyses PCG by employing ensemble empirical mode decomposition combined with kurtosis features to locate the presence of S1, S2, achieving a detection rate of 94.5%.

To diagnose pathologies from the right side of the heart we have to separate the aortic and pulmonary components of S2 and that it is a very difficult task from a computational view.

In Bartels et al. the authors explored the non-invasive BP estimation by heart sound pattern analysis. Having a total of 17 patients participating in this study, measurements of BP were made in the radial artery catheter, also gathering synchronously PCG and ECG data. Only 9 of 17 were sufficiently free from disturbances to be used to investigate the PCG features. The accentuated second heart sound of a patient was converted into a computer-aided pattern recognition process for the second heart sound. After a learning phase of the model, during which the second heart sound is recorded, analyzed and correlated with a set of systolic BP values of the individual patient (calibration phase), the computer is able to determine the future systolic BP values of the same patient from the acoustic spectrum of the second heart sound with an error of 6 to 8 mmHg (Bartels & Harder, 1992).

Figure 2. a) Filtered phonocardiogram segment; b) shannon energy segment; c) shannon energy with a moving window segment

In a different perspective Chen et al. tested a noninvasive method based on spectral analysis of S2 to estimate PAP in 89 patients with a bio-prosthetic heart valve. The technique was compared with continuous-wave Doppler estimation of PAP in these patients. The heart sounds were recorded at the pulmonary area on the chest and digitized to a computer. The spectra of S2 and its components A2 and P2 were computed using a moving window fast-Fourier transform. In Figure 2 we can see an example of a PCG signal from a patient with PAH, and an envelope calculated with a moving window over the Shannon energy; in all stages we can see S1, S2 and its sub-components A2 and P2.

Seven features were extracted from these spectra: dominant frequency of S2 (F_s) corresponds to the frequency associated with the maximal amplitude of the power spectra of S2; dominant frequency of P2 and A2 (F_p), dominant frequency of A2 and P2 (F_a), quality of resonance of P2 (Q_p), which is defined as: where $(f_2 - f_1)$ represents the difference between the frequency values above and below F_p , respectively, for which the amplitude of the power spectrum falls to 50% of

the maximal value; quality of resonance of A2 (Q_a), similarly to Q_p :

The ratio of the dominant frequencies of P2 and A2 (F_p/F_a), which can be considered as a type of normalization between patients; the ratio of the quality factors between P2 and A2 (Q_p/Q_a). The statistical analysis performed showed that the best estimation of PAP obtained by spectral phonocardiography was provided by the following equation, as evaluated by the Pearson linear correlation coefficient, with a standard estimation error of 5.6 mmHg, (Chen, Pibarot, Honos, & Durand, 1996):

In Zhang et al. the authors propose a method to distinguish the two components of the S2, which may be overlapped. For that purpose they use the matching pursuit method to decompose a signal into a series of time-frequency atoms by using an iterative process for the PCG. Compressing or expanding the frequency band of the signal can be performed without perceptible change in its spectral characteristics. It is also possible to shift a frequency band up or down to a desired frequency range without changing the temporal properties of the signal. With these characteristics

in mind their technique has been tested on 11 PCG containing heart sounds and different murmurs. The spectrogram and a matching pursuit based Wigner-Ville distribution were used for visual comparison in the time-frequency domain. The results showed that their technique is suitable and effective for the time-frequency scale transformation of the heart sounds (Xuan Zhang, Durand, Senhadji, Lee, & Coatrieux, 1998).

Xu et al. in an animal study, used a nonlinear transient chirp signal modeling approach for the analysis and synthesis of the overlapping A2 and P2 sound components of the second heart sound. This approach is based on the time-frequency representation of multicomponent signals for estimating and reconstructing the instantaneous phase and amplitude functions of each component. The basic procedure consists in estimating the component which has the higher energy first, because it is the component most easily identified in the time-frequency plane. Then, the estimated component is subtracted from the original signal, after coherent alignment using a cross-correlation technique. The method is then re-applied iteratively until all components are detected and isolated. Each component is defined by a pair of functions describing its instantaneous amplitude (signal envelope) and its instantaneous phase. In practice, the instantaneous frequency (IF) of A2 and P2 are derived from the time-frequency representation of the S2 signal and the phase functions are then estimated by integrating the IFs as a function of time. For decomposition of a multicomponent signal time-frequency this is a good tool, especially when each component is located in a different region of the time-frequency plane or has limited overlap with the other components.

They considered that the splitting interval between A2 and P2 and the exponentially decaying IF functions of both components could be advantageously exploited in the time-frequency plane to filter out and extract each component from the background noise. Since it is known that the A2 component generally appears first, its IF is estimated first using the Wigner-Ville distribution

of the S2 signal and a masking operation (time-frequency domain filter) to remove the cross terms, the P2 component, and the background noise.

The technique can also be applied to physiological signals having three or more nonlinear chirp components, but the results show that is very effective for extracting the two components, even in the presence of noise. The normalized root-mean-squared error between the original A2 and P2 components and their reconstructed versions varied between 1% and 6%, proportionally to the duration of the overlapping interval, and it increased by less than 2% in the presence of noise

The validated technique was then applied to S2 components recorded in pigs with normal or high PAP. The results show that this approach can successfully isolate and extract overlapping A2 and P2 components from successive S2 recordings obtained from different heartbeats of the same animal, as well from different animals (Jingping Xu et al., 2001).

Tranulis et al. objective was also to develop a non-invasive method for the estimation of PAP using a neural network (NN) and features extracted from the S2. To obtain the information required to train and test the NN, they conducted an experiment in 9 pigs and analyzed the heart sounds under different conditions of PAP, including pulmonary hypertension. The data recorded from each subject was the ECG, the PCG, and the PAP. Around 15 to 50 S2 sounds were isolated for each PAP stage and for each animal studied. A Coiflet wavelet decomposition and a pseudo smoothed Wigner-Ville distribution were used to extract features from the S2 and train a one hidden layer NN using 2/3 of the data. The NN performance was tested on the remaining data. NN estimates of the systolic and mean PAPs were obtained for each S2 and then ensemble averaged over the 15 to 50 S2s selected for each PAP stage. Their classification accuracy, using a 23 mmHg mean PAP and a 30 mmHg systolic PAP thresholds between normal PAP and pulmonary hypertension was of 97% and 91% respectively (Tranulis, Durand, Senhadji, & Pibarot, 2002).

In a different study, Xu et al. employed the same method as described in (Xu et al., 2003) for the estimation of PAP in animal and human subjects. It was shown that this new non-invasive method based on advanced signal processing of the second heart sound provides an accurate estimation of the PAP in those populations.

Dennis et al. study describe the development of a prototype system, called pulmonary hypertension diagnose (PHD), that uses patient data with machine learning algorithms to build models of how pulmonary hypertension affects heart sounds. They designed the PHD with three sets of parameters: chest wall location, heart sound features subset, and machine learning algorithm. In the first parameter, chest wall location, they chose 5 locations and try to determine which locations are most useful for PH diagnosis. Then they extract 46 features for each recorded heart sound in the PCG traces. Some of these features were proprietary (Inovise Medical, 2013) and correspond to the intensity or width of the heart sounds, but they also use several features already described in literature such as dominant frequencies of S2, A2, and P2, quality of resonance of A2 and P2, 8 types of ratios such as F_{P2}/F_{A2} and Q_{P2}/Q_{A2} , the splitting interval of S2, and systole duration. For the classification set 5 models of machine learning algorithms were used: decision tree, k-nearest neighbors, multilayer perceptron, naive Bayes, and support vector machine. Their main findings from the feature list were: the features extracted from the S2 sound are helpful in classifying a patient and also the percentage of the heartbeat taken for ventricular systole was much more predictive than the absolute duration time of ventricular systole, the others features had less impact on the predictive model.

The PHD tries to determine whether the PAP is above or below a certain threshold, diagnosing pulmonary hypertension in the validation set with 77% accuracy and 0.78 area under the receiver-operating-characteristic curve (Dennis, Michaels, Arand, & Ventura, 2010).

An interesting work from Angel Lopez-Candales et al. studied the split of the S2 in people with chronic pulmonary hypertension. The authors used a pulsed Doppler to measure the total duration of right and left ventricular outflow tract spectral signal to identify this narrowing between the ejections of both ventricles. Doppler data and standard measures of right and left ventricles were collected from 85 patients divided into two groups according to their estimated pulmonary artery systolic pressure (estimated by echocardiogram). Chronic pulmonary hypertension patients had a shorter total duration between right ventricle output and left ventricle output ejection time than individuals without pulmonary hypertension (-15 ± 16 ms vs. 22 ± 14 ms; $P < 0.01$), that explain the split second heart sound in chronic pulmonary hypertension patients (Lopez-Candales, Edelman, Gulyasy, & Candales, 2011).

Peretto et al. in their study present a comparison between two non-invasive approaches for the estimation of PAP. The study was conducted on 40 athletes, aged between 8 and 67 years, practicing sports at different levels. The first method uses the Pulsed Doppler which has been used for the measurement of maximum tricuspid transvalvular pressure gradient. The second method is based on the analysis of PCG sounds and particularly of the S2 and uses ECG as a trigger, extracting features from S2 and its components as suggested in previous studies. The signals were digitally acquired simultaneously, and analyzed with a software developed in LabView™. Results show encouraging matching between the two methods and also that the proposed method may be relevant for PAP estimation on athletes without significant cardiovascular diseases and practicing different sports (Peretto et al., 2011).

Chan et al. examined the relationship between acoustic characteristics of S1 and S2 and underlying cardiac structure and hemodynamics in patients with isolated PAH and controls. They did a cohort study in referral and community hospitals, evaluating 40 PAH patients undergoing

right-heart catheterization with a digital acoustic cardiography and two-dimensional transthoracic echocardiography. As control they had 130 participants without clinical or hemodynamic evidence of PAH or congestive heart failure. Ten second artifact-free recordings were selected and analyzed utilizing proprietary software with wavelet-based signal processing techniques for acoustic analysis. A time-frequency analysis allows the separation of heart sounds from murmurs and an Audicor algorithm was used to reduce external noise like speech and movement. Two acoustic cardiographic characteristics of S1 and S2 were analyzed: intensity and complexity. A value for heart sound intensity is generated based on the peak-to-peak amplitude of the sound, and complexity is determined using time-frequency measures of width, intensity and frequency content of the signal. Complexity and intensity were normalized and expressed as a ratio between S2 and S1 to account for variations in anthropomorphic characteristics. Then univariate and multivariate linear logistic regressions were applied to examine the relationship between hemodynamic variables and S1 and S2 complexity. The authors reported that acoustic characteristics of both S1 and S2 are related to the severity of PAH and are associated with right ventricular enlargement and systolic dysfunction. The reciprocal relationship between S2 and S1 complexity may also reflect the underlying ventricular interaction associated with PAH (Chan et al., 2013).

Some studies with noninvasive experiments found that the time delay from the peak of ECG R wave to the onset of the second heart sound had a close inverse correlation with arterial systolic BP (Xin-yu Zhang, Macpherson, & Zhang, 2008); Lim et al. used PCG to determine whether the ratio of S1 to S2 analyzed by esophageal stethoscope transmitted via a wireless bluetooth connection can be an accurate indicator of the BP. A total of 33 adult subjects, without cardiac disorder and with normal heart rhythm were enrolled and randomly selected to be subjects of the study,

also all patients undergo a total intravenous anesthesia induced with propofol and remifentanyl by target controlled infusion. Two microphones were used: one for the acquisition of heart sound by connecting it to the esophageal stethoscope; the other was used to measure the background noise in the operating room. After transmission of the heart sounds measured with the esophageal stethoscope to the receiver by using a bluetooth module, the portion of the recorded data through the esophageal stethoscope that coincided with the noise in the operating room was removed; noise such as the respiration sound was removed with low-pass filtering. S1 and S2 were detected with computation of the ratio of S1 to S2. Correlations between the systolic BP with S1, S2 and S1 to S2 ratio were examined. The ratio of S1 to S2 presented the highest correlation with the systolic BP (Lim et al., 2013).

Smith et al present a machine learning model based on heart sounds characteristics to estimate PAP; some features were derived from heart sounds, and machine learning techniques were applied on a large patient dataset to choose a specific model and features for PAP values prediction. Two machine learning models were tested, support vector machines and multilayer perceptron. A greedy search through the 38 possible features was conducted within the following categories; binary features, dominant frequency, quality of frequency, power, splitting interval, ratios, systole duration and heart rate, using a 109-patient cross-validation to find the most predictive features. The best model had a standard estimate error of 8.3mmHg (Smith & Ventura, 2013).

The methods presented in the literature demonstrate that several important features of the cardiovascular system may be estimated through the relations between the signals measured on the body surface; the heart sound analysis presents encouraging results for the systemic and pulmonary blood pressure estimation, however further studies are necessary to improve accuracy and validate the technique for clinical use.

SOLUTIONS AND RECOMMENDATIONS

The use of heart sounds for BP estimation is a very promising noninvasive method, however it needs to be further studied so that it may be widely used in clinical practice, and as a complement to existing methods. There are several issues in the method that need to be better understood, one of these problems, and also one of the most complex, is the separation of A2 and P2 components. Advancing the techniques for heart sound segmentation as referred earlier will allow to improve overall results; several studies use the ECG as a triggering method for heart sound segmentation, which although improves S2 detection, increases complexity of such a system. Commercially available digital stethoscopes, already define the best characteristics for heart sound acquisition, however the lack of a data collection standard tends to generate less homogeneity of the various studies. Noise interference is also a concern, and it should be controlled for better results. The definition of a data collection standard will play an important role for the success of such a system. The impact of different biotypes on sound quality also needs to be addressed, as well as the determination of the best set of parameters for BP estimation. In general there is a need for larger multicentric studies to validate the method.

FUTURE RESEARCH DIRECTIONS

To estimate BP using heart sounds there are three areas that are critical and must be extensively studied in the coming years, starting with the most complex, the separation of A2 and P2 components. Also complex enough is what kind of features should be extracted from heart sounds to estimate BP, it is necessary to look for a faster way and a more analytical method to find an optimal feature subset for on-line implementation, therefore these issues should continue to be subject of specific

and more focused studies. Finally the estimation models algorithm that best correlate heart sound features with BP also have a lot of potential to be further developed, although promising results were already achieved.

CONCLUSION

Digital phonocardiography and the analysis of the second heart sound is an evolving area; studies demonstrate that it is possible to separate the A2 and P2 components of S2, even when the overlapping interval of the two components is relatively high. Since the operating pressure and basic elastic properties of the aortic and pulmonary valves and vessels are different, their instantaneous resonant frequency functions should also be generally different. It is possible with an auscultation to determine pathologies from the left side of the heart (A2 component and systemic circulation), and from the right side of the heart (P2 component and pulmonary circulation). The advantage of using auscultation to detect heart and lung pathologies is the fact that it is a noninvasive method, with a simple and easily accessible technology. These systems could bring advantage due to its practical application, making the management of PAH patients easier, and improving patient comfort.

KEY TERMS AND DEFINITIONS

Blood Pressure (BP): The pressure exerted in the walls of blood vessels by circulating blood.

Digital Stethoscope: Equipment used to digitally amplify and record sounds from the body.

Electrocardiogram (ECG): A record and representation of the electrical activity of the heart.

Heart Sound Analysis for Blood Pressure Estimation

First Heart Sound (S1): Sound resulting from mitral and tricuspid valves closure.

Phonocardiogram (PCG): The record and representation of the heart sound.

Pulmonary Arterial Hypertension (PAH):
An increase of blood pressure in the pulmonary artery.

Second Heart Sound (S2): Sound resulting from aortic and pulmonary valves closure.

Sociological Perspectives on Improving Medical Diagnosis Emphasizing CAD

C

Joel Fisher

Department of State, United States Government, USA

INTRODUCTION

Health care costs worldwide are increasing because of new medicines, new techniques, and more expensive and extensive research on diseases. It is essential that health care delivery systems be implemented that take advantage of these advances in a cost effective economic manner. One critical aspect of the health care delivery system is the improvement in diagnosis of disease. This paper emphasizes diagnosis and the need to collect key patient information “pivotal information” at the earliest possible point in the patient’s disease process, and to put such pivotal information in physicians’ hands. There is a potential for huge benefits in cost savings and greater effectiveness of treatment from these actions, but challenges must be overcome to realize their full benefits. The major problems include (1) market incentives in the current health care system fail to encourage collecting pivotal medical information as early as possible (2) physician resistance to some of these ideas and (3) technical and ethical problems that remain to be solved.

BACKGROUND

Previously, Fisher and Fisher (2014) discussed the problems of improving medical diagnosis as both a management and information problem. Their analysis focused on three specific strategies: improving medical histories of patients by using discourse analysis, public education about

selected major diseases that if ignored can lead to health impairment and even death, and use of computer assisted diagnosis (CAD).

THE PROCESS OF DIAGNOSIS

Diagnosis is sociologically a process of bounded rationality, consisting of evidence gathering punctuated by a series of conjectures about a patient’s ills before arriving at the *best* conjecture and treatment plan. This view of diagnostics originates from Zeldenrust’s (1990) version of the garbage can model of organizational behavior that sees diagnosis as a linkage between a demand (patient with an illness) and a solution (physician guesses nature of underlying problem and offers a plan for treatment). The solution may include medicine, behavioral modification such as bed rest, change in diet etc., and perhaps tests to rule out certain competing diagnostic hypotheses consistent with applicable constraints. The physician builds on the information learned not only from the patient reports but also on test results and on other objective data obtained. The physician treats symptoms uncovered until the patient either is cured and a final diagnosis is achieved or at least until all competing hypotheses about the condition are ruled out.

Improving the diagnostic process hinges on rapidly expanding the diagnostic information available to the physician. This diagnostic information is not just any data but the sort that expands the number of hypotheses of possible diagnoses,

DOI: 10.4018/978-1-5225-2255-3.ch088

i.e. pivotal data. The physician can then examine the maximum number of plausible hypotheses. The idea is that *the more hypotheses the physician needs to rule out at the outset the more likely* the physician will find the disease(s) behind the patient's complaint and provide the proper treatment (including referral for specialized services). The process also covers multiple possible pathologies that may exist at any moment, although the clinician may place ordering priorities on these possible multiple pathologies.

A. The Medical History and Discourse Analysis

Medical authorities agree that the most important basic information beyond a description of the patient's medical complaints is the patient's health history. An encounter with any provider usually begins with some kind of questionnaire or interview with regard to that history. The needs of different providers often result in different kinds of questionnaires or approaches about health history. They likely cover all the same major issues, but the differences can be important. There is little evidence that these initial interviews involve people trained in discourse analysis. Since the Fisher and Fisher (2014) analysis, almost no real advances or progress have been described. In fact, clinical people are almost expected to develop interviewing skills by "osmosis" on the job. A surprising finding was that neither nursing nor medical curricula include formal course work on this although some medical schools give orientation lectures and guides to such interviewing skills. The technique is not included in the so-called "patient assessment courses."

Discourse analysis, popular in the United Kingdom, is basically the study of language in context (Elwyn and Gwyn, 1999). The subject shares much in common with assessments of communication that look at gestures (often referred to as "body language") –the "silent language" (Edward Hall, 1973). The discipline examines conversational processes: how is one version of events selected

over another? How is a familiar reality described to give it an unquestionable authority? It then brings to bear on the patient's diagnosis *all the information* that patients are providing, and *saves it for future use*. It can identify and elicit previously hidden patterns and perspectives (for example, in patient clinics, among health visitors, and in transcripts of interviews conducted by HIV counselors). Their extensive list of references suggests that the technique has been widely applied in health care related situations with promising results.

The technique has a sound basis in social science and can be applied quickly by medical practitioners and should be included in the basic course work of the field. Discourse analysis seems to be easiest to implement in medical practices serving ethnically relatively homogeneous areas whose residents have a relationship with the medical staff. This has major implications for CAD.

B. Public Education

Although public education is not a diagnostic procedure, it garners public cooperation in early diagnosis and treatment of many serious illnesses. Its purpose here is not to impress on people to take better care of themselves, but rather to have targeted campaigns about specific conditions that if treated early are easily cured or managed, but if ignored, become extremely expensive to treat and perhaps lethal. Public education should put *pivotal* information in the hands of both the physicians and patients as early as possible in the disease process to maximize the probability of effective treatment at the lowest possible cost.

Patients who recognize the possible variety of symptoms of heart attack and stroke etc. will more likely seek treatment when the physician's intervention may be most certain to work, and probably least expensive. Some diseases, such as colon and pancreatic cancers often show few or no early warning symptoms and only make you uncomfortable enough to seek medical attention in their advanced stages. These diseases typify a propensity of people to avoid medical attention

until they are in pain or their normal functioning seems to have been greatly impaired. Much current public education work seems to have a “disease of the month” flavor, reflecting what specific illnesses have become objects of attention in the news media.

C. Computer Assisted Medical Diagnosis (CAD)

The most important suggestion is CAD, and it is where the most progress has been made. CAD does not diagnose the problem but only suggests a range of hypotheses for the physician to check out. Put simply, computerization of the diagnostic process might advance medicine by looking at individual symptoms, clustering symptoms, and providing a kind of pattern matching algorithm that generates the needed conjectural hypotheses consistent with the information in the medical data banks.

CAD offers the major advantages of a nearly unlimited virtual library or information facility, a communications facility, and an inexpensive infrastructure. Scadding (1967) hoped that physicians would soon take advantage of the possibility of instantaneous correlation of groups of clinical and laboratory findings with the established features of specific diseases. Physicians would also capitalize on the computer’s ability to *suggest* a wide range of possible diagnoses without necessarily discriminating among them although it could include risk assessment algorithms that rank them by probability of occurrence and seriousness of outcome if left untreated). These special information tools have become a major focus for big data and information specialists in many fields.

When Fisher and Fisher (2014) examined the issue a universal CAD system did not exist in the United States. Early considerations by the military to develop one remained basically in the conceptual stage. There is still none, but a review of CAD systems at large indicated a number of interesting findings.

1. The most widespread and successful medical CAD usage has been in medical imaging, a highly limited area of diagnosis. Qiang and Nishakawa (2015) have produced a state-of-the-art compendium of its use for various types of imaging to detect and evaluate carcinomas. That may highlight the difficulties in expanding the tool to a wider area of medical diagnostic concerns. Watson, a supercomputer from IBM, involves a look at diagnosing certain kinds of cancer. (Mearns, Lucas, 2013) One of the tasks of Watson is to continuously update and comment on the literature. The scientists working on Watson hope to make it widely available soon. Watson’s developers at IBM mention that its major feature is that it can focus its massive data processing capabilities on personal genomes. Note, however, that work involving the human genome tends to raise certain ethical and privacy issues, major sociological concerns. In looking at a CAD system, one is really not currently easily able to relate to the sociological issues of privacy and ethics beyond indicating that the operation and access of the system to information be in accord which respects privacy and adheres to ethical norms.
2. A CAD system has been used extensively in France (Seka, Fresnel et al, 1997) and the French researchers have proposed expansion for the Internet at large. Although France has a diverse ethnic and demographic population, compared to the United States’ diversity of ethnic and demographic features, the French might be considered a somewhat ethnically and demographically a smaller, possibly homogenous cultural unit. The French system accommodates information on about 10,000 diseases. This may or may not be a suitable number for system guidelines, but since various forms of cancer, a disease with probably the most variations and types has over 1,000 separate disease designations, it may be satisfactory.

3. Various groups are using CAD systems in rural India and areas of sub-Saharan Africa where the medical problems have unique geographic and ethnographic features. (Kalode, Kempar, and Deshpande, 2012; Friedman, 2009). A major thrust in CAD systems for diagnosis is for rural areas that are medically underserved mainly because sociologically this is not an area where clinicians seem anxious to practice. It often lacks infrastructure, access to researchers and research facilities, and other desirable features.

The *sociological* implications are that a *universal CAD may not necessarily be either optimal or desirable*. Rather, one might develop a series of CAD systems related to smaller regions with ethnic, geographical and demographic unique considerations as well as the most common pathologies universally encountered, unique to certain regions with a subroutine to search other systems based on information in a patient's history about travel, residency and other factors that may become important. This is the most important new direction that this diagnosis work should take.

CAD's biggest technical hurdle is the fiendishly complex nature of a diagnosis (see: Innocent & John, 2004). Some symptoms, such as fever, are always important; but for other symptoms the importance depends on context. An effective CAD in generating hypotheses will include a provision to note that certain symptoms are especially significant in the presence of others in confirming a diagnosis.

The many and diverse bases for deciding a disease behind the symptoms include cause, description, site, symptom/syndrome, variation from statistical norm, and treatability. Further, diagnoses change as individuals, professions or society dynamically modify the boundaries of what they consider respectively normal or problematic. For example, not all physicians accept chronic fatigue syndrome or even fibromyalgia as diseases. In the 1970's United Nations publications listed

world-wide fatalities from juvenile prostate cancer as a single cause of death, but the most recent compendia list over six different categories of the disease. Psychiatric disorders continue to be sources of controversy as to what is a symptom or syndrome or condition. This has even prompted legal arguments as to the legitimacy of certain diagnoses. These are mainly *social issues*.

Jutel (2011) endorses Aronowitz (2001) that *social influences* have largely determined which symptom clusters have *become* diseases. CAD may not cover every condition that physicians treat because no societal or professional consensus exists as to whether the condition is a disease and to what is its appropriate treatment. That fact should not inhibit CAD. Computer programs can assign conditions with appropriate data in special categories where there is no societal or professional or societal consensus, or such identity has not been sought or even rejected. A CAD system should accommodate certain symptoms or syndromes as identifiable even if they are professionally not recognized, simply because they occur so often that to ignore them is foolhardy. The patient still suffers from the condition regardless of any societal or professional agreement as to the legitimacy of the diagnosis.

CAD can assist in reducing misdiagnosis. Since the Fisher and Fisher (2014) paper, this has become something of a two-sided issue. On one side, CAD can offer a comprehensive list of hypotheses and indicate what additional pivotal facts, such as test results, are needed to confirm each of them. On the other side, there seems some feeling that reliance on CAD could result in increasing errors of medical malpractice. Several websites of attorneys have appeared recently soliciting clients who may have been improperly treated because the diagnosis and treatment were traceable to hypotheses of recommendations from a CAD system. This should not discourage development of CAD because it only provides information, it does not formally diagnose.

In discussing misdiagnosis, Bradley (1993) found that the physician typically begins with three

or four hypotheses but rarely more than seven. He counsels physicians who cannot avail themselves of a CAD that one of the four hypotheses should be a “catch-all”— *i.e.* any of the above, or even none of the above. There needs to be considerable computer work to specify the features and operating protocols for this “catch-all” category.

When facts support one of the three starting hypotheses, it is important to maintain the possibility of the true diagnosis being something else. Good diagnosticians do this, or something akin to it. The author of this paper lives in an area characterized by a fungal disease known as “Valley Fever.” It has symptoms that may suggest flu, various kinds of pneumonia, tuberculosis, unusual allergy situations, certain kinds of seizure disease orders and a host of more common ailments (Malo et al, 2014). A CAD system for the physician in this area should include Valley Fever in all proposed hypotheses if the symptoms comport. Another disease that has caused similar misdiagnoses because of its many symptom manifestations is Lyme disease (Pachner, 1989; Stanek, 2012; see also fact sheet from CDC, 2015).

Pivotal facts often differ between men and women. Recent studies have shown that men and women tend to present different sets of symptoms for heart attacks and strokes. These gender differences require considering more possibilities when certain symptoms are present. Campbell (2015) has written extensively on this issue with respect to women’s heart conditions.

Sometimes a misdiagnosis arises from prematurely accepting a positive confirmation of an initial. Bradley warns physicians to guard against misusing information by over-emphasizing positive findings when a negative finding may be just as diagnostically significant. There is a natural tendency to prefer positive evidence proving a hypothesis over negative evidence disproving it. A test that could confirm a diagnosis because of a positive outcome tends to mean that the assumed diagnosis that called for the test is likely to be correct. However, to improve diagnosis, a negative test [finding] should have the converse effect of

making the original assumed diagnosis less likely. Bradley notes that often the clinician ignores this negative evidence. The disease often gives negative or ambiguous test results from immunological and serological studies despite a patient having the disease). This becomes especially important when the confirming test result is subject to a false positive error, or when a confirming test result can also suggest other hypotheses, which may or may not have been in the original cluster of assumed diagnostic conjectures. A CAD should include a feature that alerts the provider with guidelines to question if a particular result may originate from assuming that a certain diagnosis is confirmed by a certain test.

A negative finding does not always disprove a diagnostic conjecture. Many patients are asymptomatic for certain conditions and a particular test may prove negative for that person even under the condition it is designed to highlight. [see references on Lyme disease at end of paper, Pachner 1989 and Stanek, 2012]. This author had *normal* sinus rhythm from an EKG while having a near fatal heart attack, and only a physician’s recognition of other signs led to a life saving diagnosis.

CAD can reduce misdiagnosis by having a “parallel testing feature”— it can offer a list of hypotheses fitting the same set of facts. A physician not accessing a CAD may settle on just one of the possible hypotheses (without ruling out the others) and choose the wrong one. The frequency of such situations of misdiagnosis is unknown, but missing the correct diagnosis of a disease such as MDR tuberculosis as a possible tropical parasitic infection has serious public health consequences (Naik, 2012).

A CASCADE OF SMALLER CAD SYSTEMS AND A SUPERCOMPUTER

Computer technology continues to advance at exponential levels. The computers have greater storage, more flexibility, smaller sizes and a host of great features which should now be augmented

with the diagnosis requirements. There is a need to link smaller CAD systems individually emphasizing regionally specific diseases into a cascade, or through access to a supercomputer designed to obtain information needed for a patient with an unusual history of travel, residence, or other factors. By keeping local systems small, they prevent management overload with regard to information, and minimize problems related to network function and oversight for the clinician.

The local systems can include provisions for symptoms and diseases which have not yet received either professional or social acceptance or those being debated at various professional levels of practice. The local systems can also indicate which techniques, tests, and protocols are experimental, or have not received peer review but are still in use. The larger system can provide information as to the status of any disease or treatment with regard to national or governmental authorities, both locally and internationally, and provide for appropriate mechanisms of information translation where the local CAD system has linguistic differences from another CAD system's language of inquiry.

Many current medical systems have enhancements that allow patients to access their medical records from home computers and "smart phones" though "patient portals." This technology also allows rapid conferencing among medical colleagues. This could reduce some costs associated with second opinions needed for a diagnosis and increase the quality and extent of care available in medically underserved areas by focusing on the kinds of consultations needed. The patient portal approach could make the CAD usage patient friendly. The proponents of Watson see this as one of their major goals.

CAD can foster major infrastructure improvements. CAD can provide links to consulting physicians in distant medical centers to augment a health care provider's local network. One major system links physicians on call in Australia and Europe to provide 24 hour consultation possibilities because of time zone differences and working hours in the

United States. Even diagnosis and treatment in outer space is possible, as astronauts can follow instructions from remote centers on earth to deliver health services to others in space with them. And we should not overlook the benefits to doctors in medical centers who deliver much of the health care to people who use the emergency room as their family physician.

FUTURE RESEARCH DIRECTIONS

Getting wider physician use of a CAD may be a problem, although this author believes that the physician resistance to CAD as machine replacing their work is largely unfounded. Even if the profession's leading members endorse CAD, others might not readily fall in line. The current United States approach is to produce "best practices" papers and manuals to reflect the new knowledge. Professional societies have taken a positive lead here, but some government agencies, notably the Veterans Administration, see the need for these documents as internal procedures and protocols and have made their use more accepted and widespread. CAD can act as an assistant in producing these documents through its information archival capabilities, as well as by incorporating the results of these documents to assist clinicians when looking at possible hypotheses of diagnosis and treatment.

CONCLUSION

The importance of good diagnostic tools will go far to improve health and health care delivery systems in a new environment of high medical costs, special insurance requirements, record mobility and big data usage. Because quantity and quality of medical care are not evenly distributed in the United States, one way to improve the quality across the country is to focus on improving the accuracy of and speed with which physicians make diagnoses.

A comprehensive CAD offers the current best hope to improve diagnosis. The tool need not be perfect to be valuable in reducing physician diagnostic errors and in making more precise the needs for consultations and second opinions, and possibly in speeding up diagnostics.

The most useful and successful CAD systems for other than special technical protocols or single diseases, are regionally specific. That seems the key to improved diagnostic usage. A series of smaller CAD systems should emphasize the diseases unique and common to certain areas. These smaller systems can contain linkages to other systems or a supercomputer when the patient information, either from medical history or encounter questionnaire/interview shows residence, work, and travel or simply traversing certain locations which feature diseases whose symptoms may confound others or offer additional hypotheses in a specific diagnosis.

INTRODUCTION

In some ways it is easy to see the impact cloud computing has had on the way people interact with technology. Users need not depend on a single device, but can instead access their data from a range of devices. Someone may for instance begin working on a presentation on a PC, continue working on it on a tablet, and decide to do some light editing on a smart phone. When people purchase a new phone these days, they need only to link it to the appropriate provider in order to access their contacts, calendar and other data, whether it be documents, photographs or financial statements, and they can exchange one device for another seamlessly and still be able to do what they wish to do. If an individual device fails, it may be inconvenient, but ultimately it does not destroy data or prevent access to it from another device, as one or more third-party providers hold an up to date copy of the data somewhere. Everyone can see these changes, what is not clear are the underlying enabling technologies that make this all possible and how organizations can best leverage them.

BACKGROUND

A common view of the cloud is that it is nothing new, that people have been using centralized computing in the form of mainframes for instance. While this sheds light on some of the similarities between mainframes and the cloud, it does not reflect the differences between them, differences that are significant. One useful analogy is to compare the cloud and earlier technologies, with the smart phone and the traditional telephone. While the telephone as such is not new and the smart phone

can do the same kinds of things as the traditional phone, it is much more flexible and powerful, and this is down to, in large part, how mobile devices take advantage of the cloud, making them more functional and helping extend battery life (Liu, Chen, Ma, & Xie, 2016). As a term “cloud computing” is problematic because it does not mean one thing, but is “an umbrella term” (Missbach, Stelzel, Gardiner, Anderson & Tempes 2013) that refers not just to a set of technologies but a new model of delivering a wide range of computing resources, services and solutions.

Fortunately, the National Institute of Standards and Technology (NIST) has made a deliberate effort to define cloud computing and done this well, so much so that its three-page description of this term is now considered the standard for the industry. NIST defines cloud computing as “a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction” (Mell & Grance, 2011). This definition is comparable to the four key characteristics of cloud computing as “pay-per-use”, “elastic capacity and the illusion of infinite resources”, a “self-service interface” and “resources that are abstracted or virtualised” (Voorsluys, Broberg, & Buyya, 2011). The cloud is “ubiquitous”, “convenient”, and “on-demand” in the sense that users can access applications and data from anywhere and at any time, and because organizations (or “customers” as the literature often calls them) can, without having to talk to anyone, provision computing resources and services from a “shared pool of configurable computing resources,” a busi-

DOI: 10.4018/978-1-5225-2255-3.ch089

ness model that involves renting multi-tenanted infrastructure.

SERVICE MODELS

Cloud providers, through the use of virtualization, essentially abstract the software, whether it be a server, a database or a network from the underlying physical infrastructure, and offer customers logical software-defined computing resources and services that they can customize, secure, provision and manage in a way that meets their needs and requirements (Buyya, Vecchiola, & Thamarai Selvi, 2013). The service models in cloud computing all reflect this principle of abstraction and represent different sets of responsibility depending how much or how little customers wish to outsource. Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) therefore represent progressively lower levels of engagement on the part of customers, as they cede more of their responsibilities to the cloud provider.

With IaaS, customers no longer need to purchase physical equipment and associated infrastructure, and manage it, whether it is a server in the case of a small business or a large datacenter in the case of a large business. They can instead utilize the provider's resources presented to them in the form of *virtual* infrastructure such as virtual machines (VMs), networks, storage, firewalls, and load balancers, all on a granular pay-as-you-go basis, so that the customer pays for example for each hour of use of a small VM, which will be cheaper than a more powerful VM. While the benefits outweigh the constraints, customers need to know not just what the provider can but also what it cannot do and work within the limitations of a particular cloud. For instance, in Microsoft Azure once a virtual network has been created it is not possible to add a virtual machine to it. There are workarounds, for instance keeping the disk with the data and connecting them to newly created VMs in the existing virtual network.

In the case of PaaS, customers have no access to or control over not just to the underlying physical but also virtual infrastructure, such as servers, networks, storage and operating systems. PaaS involves the provision of resources and services, such as a development environment, database, and integration and development tools that can be used in a matter of minutes, all provided so as to reduce the effort and cost for SaaS vendors (Brown & Nyarko, 2013). Customers can instead focus on the functionality and logic of applications. It is the responsibility of the provider to ensure that a database for instance can cope with the increasing demands made on it and that the underlying operating system is properly patched and secure. Well-known examples of PaaS are AWS Elastic Beanstalk and Force.com (part of Salesforce.com). In terms of IaaS and PaaS, Amazon Web Services (AWS) is currently the largest public cloud provider and Microsoft the second largest public cloud provider, with 57% and 20% of enterprises making use of them respectively (RightScale, 2016). This is in line with the Gartner magic quadrant (Leong, Toombs, & Gill, 2015).

SaaS is a fully-built software solution that customers can use immediately. It is an application that is owned by the provider, who takes responsibility for all aspects of its development, deployment and operation (Carstensen, Morgenthal, Golden, 2012) as well as for security, performance and availability. The application is accessed through a network connection by the customer, who usually pays a subscription of some kind instead of the traditional upfront license fee, which costs a great deal more because it gives the customer a permanent right to use the software whereas the subscription does not. The application or set of applications is hosted on a remote system and the customer data is stored by the provider but the customer can access the application or set of applications and the data from various devices and systems. Well-known examples of SaaS are Microsoft Office 365 and Salesforce.

DEPLOYMENT MODELS

NIST identifies four cloud deployment models: private cloud, public cloud, hybrid cloud and community cloud (Mell & Grance, 2011). The private cloud is owned and operated by a single organization that may have various customers, such as departments or business units. The organization is completely responsible for managing all aspects of the private cloud: procurement, configuration, maintenance, support and delivery of services. As a result, there are usually few significant cost savings or economies of scale or pooling of resources typical of the public cloud. Some commentators argue that few organizations will implement an on premise cloud environment that satisfies the NIST definition because that is not only expensive but is also technically a highly complex undertaking (Golden, 2015). When most people refer to the “cloud,” they are thinking of the public cloud, a cloud entirely owned and managed by an external third-party provider. In most cases the public cloud involves shared third-party infrastructure, though exceptions can be made for those customers willing to pay a premium for hardware dedicated for their exclusive use.

The hybrid cloud acknowledges that most organizations would wish to continue making use of on premise infrastructure that current IT staff know and understand while being able to take advantage of the public cloud and associated services. While the hybrid cloud is meant to be a private cloud that expands into the public cloud, in reality it may not entail the use of a private cloud at all and may instead simply be a more traditional on premise virtual infrastructure that connects securely with one or more public clouds to form a single hybrid entity. One example of this is the use of compute in the public cloud while retaining data on local on premise systems. Another is the use of SaaS that integrates seamlessly with existing environments. This is now being extended to the connection of not one but multiple clouds as various companies take the view that most organizations are likely

to make use of a number of providers and that these clouds need to be connected seamlessly (Schwartz, 2015).

The community cloud is typically a private cloud in which a number of entities share the cost and benefits, while avoiding some of the concerns around security and regulation associated with the cloud. This works best when the entities share similar security, governance and policy requirements (Bond, 2015). For example, multiple government agencies may make use of a single datacenter, with the result that less of their interactions have to traverse the internet (Winkler, 2011). While this satisfies regulatory and compliance requirements, it is not elastic, not necessarily highly available, and is typically only IaaS, with managed services having to still be built and maintained. The community cloud, though, may also be part of an external, public cloud that has been especially designed and provisioned for that purpose. The Microsoft Office 365 Government Community cloud is an example of this. It satisfies a particular set of requirements: data is stored in the United States, customer data is restricted to screened Microsoft personnel and satisfies all the requirements of US public sector customers (Microsoft, 2016).

SECURITY IN THE CLOUD

When organizations adopt the cloud, much of their network, systems, application and data moves out of their immediate control and becomes the responsibility of the cloud service provider, something that clearly has profound implications for security, compliance and governance (Kale, 2014). The multi-tenant model of the cloud requires customers to trust providers, and not just with the orderly functioning of their operations but often with private data and intellectual property. The responsibility for security in the cloud is shared between customer and provider. With some of the security being the responsibility of the cloud

provider and some of the security being the responsibility of the cloud customer. It is important that the customer understands, this demarcation line otherwise known as the “trust boundary”, since this involves having a good grasp of the scope of management and monitoring responsibilities. Moreover, the trust boundary changes depending on the service delivery model, the service level agreement and the provider’s approach to security (Mather, Kumaraswamy, & Latif, 2009).

With data being handled and stored by third parties, security, regulation and compliance considerations are vital. One widely-used standard is the Payment Card Industry Data Security Standard (PCI DSS), which applies to organizations that handle credit cards and specifies how personally identifiable information (PII) is stored and accessed. Another is the Health Insurance Portability and Accountability Act (HIPAA), which now designates providers as business associates of customers and therefore requires them to also be HIPAA compliant. These and other standards ensure operations are more secure but at some point organizations also have to trust the cloud provider. Security is often cited as a barrier for adopting the public cloud, and certainly in the past many customers have struggled with this (Carstensen, Morgenthal, Golden, 2012). Yet while organizations lose total control of security, the fact is that large cloud providers draw extensively on the best security expertise and practice, so as to ensure that their side of the trust boundary is as secure as it possibly can be, so that IT operations as a whole are more rather than less secure. As Rob Alexander, chief information officer of Capital One put it, “We can operate more securely on AWS than we can in our own data centers” (Krazit, 2015). There is some evidence to suggest that these days security in the cloud is no longer the challenge it once was, with the major issues for organizations being instead a lack of resources and expertise (RightScale, 2016).

FUTURE RESEARCH DIRECTIONS

C

Some people continue to express reservations and concerns that not only does cloud computing raise difficult questions related to security but that reliance on a small group of large cloud providers also threatens the essential openness and innovative nature of the internet (Anderson & Rainie, 2010). Other questions need to be looked at, most particularly how providers can best interface not just with customers’ devices but also with one another, as increasing numbers of customers’ systems and infrastructure utilize multiple providers’ clouds. What is clear, though, is that demand for and use of cloud services is rapidly increasing. Within a short time for instance few organizations will run their own email systems and most email will be stored in and accessed from the cloud. In addition an increasing number and range of products from health monitoring implants to sensors in cars and buildings will rely on cloud computing. One of the critical areas requiring scholarly attention is how government can create a sufficiently robust regulatory environment that will adequately protect customers, even though systems and data in the cloud traverse national boundaries and jurisdictions. These are as much philosophical as they are technical questions but they demand urgent study and investigation.

CONCLUSION

There is, strictly speaking, no such thing as “the cloud”. There is not one but many clouds, with providers aiming to make customers more effective and competitive through the use of a wide range of services, including account management and billing, identity and access management, databases, developer tools, monitoring and a range of applications. Increasingly the cloud is mission critical for customers, whether these are individuals, small and medium-sized businesses

or large corporations. It started mostly with test development environments and its use is expanding to increasingly diverse range of uses. The cloud increases access to resources that scale, but also masks even eliminates for customers much of the technical complexities and drudgery of running on premise infrastructure. Customers no longer need to manage hardware and licensing and have only to pay for the resources they use while being able to operate efficiently through the use of automation (Winkler, 2011). They can also immediately leverage large cloud providers' infrastructure to deploy applications easily and rapidly across multiple geographic regions. In 2014, there were twenty times more active VMs in the public cloud compared to 2011 (Bittman, 2015), making it clear that while the use of on premise infrastructure and private clouds has increased, the greatest growth is from customers seeking to move new workloads to the public cloud.

When organizations adopt the public cloud, not only are they able reduce the complexity and cost of operations, they also gain, through the provider, much greater flexibility, elasticity, and scalability. Storage, compute and networks can be "rapidly provisioned and released" (Mell & Grance 2011) because interaction with the provider is minimal and operations are streamlined to maximize efficiency, including typically the use of standard service terms, service-level agreements (SLAs) and limitation agreements. This increased flexibility does raise challenges in terms of data security and access control because users store data and then share it with others who are not necessarily in the same trusted domain, but then staff managing on premise infrastructure face the same kinds of challenges, often with a great deal less support from third parties. As one provider put it, the reason to move to the public cloud is "to lower costs, reduce complexity, and increase flexibility" (AWS, 2015). These factors will likely continue to drive growth in the public cloud over the next few years and beyond.

KEY TERMS AND DEFINITIONS

Cloud Deployment Models: The way in which cloud services are provision, for instance the private cloud, the public cloud and the hybrid cloud.

Cloud Service Models: The distribution of responsibilities for technological requirements between customer and cloud provider.

National Institute of Standards and Technologies: A federal agency within the U.S. Department of Commerce that is responsible for measurement science, standards and technology.

Service Level Agreement: A contract that defines the level of service the customer can expect from the cloud provider.

Trust Boundary: The boundary between the responsibilities of the customer and the responsibilities of the cloud provider.

Virtual Machine: A guest machine that is capable of sharing the same physical hardware with another guest machine and runs on a hypervisor.

Virtualization: The division of a computer into multiple execution environments so that one level (e.g. the physical) can be abstracted from another (e.g. the operating system).

Cloud Governance at the Local Communities

Vasileios Yfantis
Ionian University, Greece

INTRODUCTION

The public organization is an organization that operates as both physical and virtual entity because the citizens' service is implemented on both ways. The physical infrastructure includes all the physical offices and processes that the government uses. Consequently, government as a virtual organization should adopt the most characteristics of a virtual organization in terms of infrastructure. According to Lee and other scholars (Lee, 2014) a virtual organization is «a security and collaboration context not exclusively associated with anyone physical organization». In other words a virtual organization may be considered as a different entity than the physical organization. If a virtual public organization is not associated with the physical organization, might confuse the citizens. On the other hand, the virtual form of the public organization can offer services than the physical one is not capable of offering. For instance, a virtual organization can offer the services of the virtual authentication and digital signature on 24/7 level. It is obvious that a virtual public organization transforms the government into a set of electronic services.

Government as a Service is a terminology that describes a governance model where cloud computing (Ostermann, 2002) is an important element in the operation of the public sector. Modern society promotes the service oriented concepts as the fundamental principles for the future of the global economy. One very promising concept being implemented is the Software as a Service (SaaS). The platform that is being used for its implementation is cloud computing.

GOVERNANCE AS A CLOUD COMPUTING SERVICE

In this section we are exploring the concept of community in order to improve Government as a Service.

Community cloud computing and cloud computing have the same philosophy; they distribute software, hardware and application resources among users. According to Manion (2004): «People in a country with a high degree of political freedom can participate in the political process more openly and actively, which in turn helps alleviate corruption by empowering people to monitor the exercise of the official power». At community level, it means that if people participate in the electronic governance of the community, then they can help in the minimization of the corruption. This is an important reason in order to explore the actual participation of the autonomous community in the electronic governance. There are two types of community cloud computing that depend on the management of the server side components (Badger, 2011):

1. **On-Site Community Cloud:** The management and the maintenance of the server are being implemented by the members of the community.
2. **Outsourced Community Cloud:** The management and the maintenance of the server outsource to a private company.

These two types of community cloud computing are going to influence governance in various levels regarding its distribution and application.

DOI: 10.4018/978-1-5225-2255-3.ch090

Figure 1. On-site community cloud computing

The most interesting example is the case of self governed communities such as small municipalities or villages. Users could be divided into those who only act as citizens and those who manage the server's tasks, but remain citizens as well (Figure 1). It is important that everyone is obliged to obey the rules of the community.

The IT literal members will take over the technical tasks with a number of members assisting to routine technical operations; everyone is able to enjoy the citizen's services. The bond is strong as long as each individual member focuses on the governance mission of the community and acts responsibly. The responsible behavior of the community will trigger the responsible application of the citizen's rights. So, the more respect the members show to the community, the more

respect will show to the public sector. Realizing this fact, governments will try to form a new generation of responsible citizens through training and educational school programs.

The adaptation of the outsourced community cloud model by the citizens offers them greater independence (Figure 2). The server's maintenance will be outsourced to an external company and the community members will focus on the responsible action of the citizen rights and their cooperation with other communities; a business model could be developed in order to allow access to their governance's best practice to other communities under a subscription agreement.

The governments need a serious amount of computing resources and different applications to use. Community cloud allows citizens to share

Figure 2. Outsourced community cloud computing

resources and save money minimizing the use of expensive software and hardware. Last but not least, communities will be able to rent part of its computing resources to other communities.

The fact that each community has a common mission and members with common needs, leads to the adoption of a custom cloud computing system which satisfies their particular computing needs. The community of citizens, just like every other community features these characteristics (Anderson, 2008):

1. **Access:** Every member of the community has to be authorized to access the community's resources.
2. **Communication:** The members of the community have to communicate with each other.
3. **Presence:** The members of the community have to establish relationships between them.
4. **Involvement:** Every member of the community has to participate in the activities of the community.

Gerald Briscoe and Alexandros Marinos note that the features of a community cloud computing include (Briscoe, 2009):

1. **Openness:** There is an open source concept because there are no restrictions with the major cloud computing vendors (Krutz, 2010).
2. **Community:** The technology infrastructures shares common characteristics with the social structure.
3. **Graceful Failures:** The cloud is not owned by a specific company; therefore the risk of failure is minimized. The community cloud is consisted of nodes which function independently, so if a node collapses the failure would be "graceful" because the system will continue its operation, and gradually will recover, almost eliminating the downtime (Birman, 2012).

4. **Convenience and Control:** There is no conflict between convenience and control because they are distributed equally among the community.
5. **Community Currency:** The users of the community are able to define their own currency for the use of the service. This currency could be financial aid or a voluntary technical task (Soder, 2008).
6. **Environmental Sustainability:** The community cloud computing is an environmentally friendly system. Each member of the community uses the exact amount of energy necessary to service its needs, so as to ensure the scalability of the available resources (Wang, 2011).

Adopting the community cloud computing in the citizen's community makes citizen's action a communal service with the following characteristics:

Citizen community's access and community cloud computing: The open architecture of the mobile cloud computing makes the access to the public documents easier by minimizing the access restrictions. The members share common needs and a common citizen mission, so they know what to expect from their participation in this community.

Citizen community's communication and community cloud computing: Communication between the community members is the key function to share information about new laws or measures. The convenience and control over the file sharing that the community cloud computing offers to the community members could trigger the exchange of new public documents as well.

Citizen community's presence and community cloud computing: Trust is one of the most important values in the personal relationships as well as the economic transactions in the human society. In a citizen community the file sharing between the members could lead them to organize social gatherings, conferences and other com-

mon interest political activities. The structure of the community cloud computing allows users to be “friendly” with the other members; which improves the social bonding.

Citizen community’s involvement and community cloud computing: In a citizen community every member has to be active so as to contribute to the quantity and quality of public documents sharing within the community. The graceful failures of the community cloud computing are a sign of warning for the contributing members, in order to participate vigorously and avoid destruction.

The currency of the community cloud computing might be anything that helps the citizen community’s functionality. This means that the citizens will save money from their financial obligations to the government if they volunteer to do technical activities. The community will be divided into teams and each team will undertake a technical task: e.g. Maintenance of the server, back up duties, application testing and much more. This is an ideal advantage of the community cloud that will benefit the participation of the community.

The operation of the cloud is distributed to the community’s resources, so it doesn’t require expensive machinery and the use of excessive power to function. These environmentally friendly techniques could be a drawing power for potential users who are sensitive to such matters.

FUTURE RESEARCH DIRECTIONS

Data sharing is a familiar practice to Web 2.0 users. However those who are looking for the next trend, have already seen the emerge of the Web 3.0 era which is known as semantic web (Allemang, 2011). How Government as a Service will be conformed to the world of Web 3.0?

Semantic web defines simasia (meaningful value) to sites’ content so that these can be reused predictably by modalities to satisfy human needs. A current keyword search using a web search engine will show results that include the keywords but not the simasia of the question of the user. For

instance a question such as “which is the fastest administrative act regarding the family status?” cannot be answered efficiently by the existing web intelligence; humans have to study and evaluate results, exclude choices, further elaborate their search criteria. Semantic web mining engines promise to extract simasia out of the question and compare it against simasia extracted from RDF structured content.

Ontologies are being developed to define meaning so that semantic mining is applicable. The semantic web mining technology results to greater satisfaction among the members of a cloud community that will trigger more requests for the public services. At the same time more satisfaction and less time needed for the issuing of public documents leads to more community members; the more the members the more the computing resources to support the user’s needs. Communities will start lending computing resources to each other and get ready to answer to such question as “lend me for k weeks the appropriate computing resources to efficiently provide the x documents to my members”. Part of the previous question refers to the computing resources that need to be calculated and offered to another community. We envision a semantic mining engine able to assist us in such questions. Perhaps this is a post semantic web evolution.

Semantic web research efforts share the following characteristics (Stumme, 2006):

1. A common syntax for machine language oriented phrases.
2. A common vocabulary.
3. A common logic language.
4. The usage of the language for exchange of proof.

Most researchers nowadays focus on the meaning of the web page’s data while building a search engine, a post semantic web will also is able to calculate the requested computing resources. E.g. A post semantic web engine will not only but be able to answer the question “which is the fastest

administrative act regarding the X process?” but will come up with results to the question “which is the fastest administrative act of the X process and what is the bandwidth needed for the issuing of the document in real time for forty users?” The development of a hybrid semantic engine that will be able to search for a specific public document or combine public data with the computing resources needed for their support, is the key to continue sharing information in an advanced web. The implementation of such a hybrid semantic engine requires a suitable ontology driven language.

Except the technical research direction, there are legal concerns as well about the use of the community cloud computing in the public sector (Winkler, 2011). The fact that the citizen’s data do not remain in a local system, but they are archived in the cloud, it raises a legal concern about who is the authorized user to access and edit this data. From the government’s side, it is important to ensure that will secure the privacy of the data by establishing an appropriate agreement between the government and the cloud computing vendor. The terms and conditions of the agreement should clarify the authority about the control of each party over the citizen’s data and have to ensure a specific service level from the vendor’s side. In terms of security, there should be defined a process about the vendor to notify the government in case of unauthorized access to the data by hackers or requests by foreign governments about access to the data (Snooks, 2012). In confidentiality level, the vendor should be aware of the confidentiality degree of each set of data in order to manage the data in the appropriate way.

CONCLUSION

Cloud governance is a concept that has to be adjusted in the new challenges of the Information Technology. The application of e-government in the autonomous communities through cloud

computing is a way to reduce the corruption and empower the bonds between the members of the community. On the other hand, the communities have to use the advantages of the cloud computing in an ethical way. The recent findings that ISIS was using a network of playstation devices for the communication between the terrorists, is a sad fact. I wonder if a Community cloud computing network would be a strong weapon for the terrorists. The question here should be how secure is a community cloud network and what is the mission of this type of network?

However, I believe that the issues of unauthorized access to secret information and the website hacking actions will be reduced if the Government as a Service model will be developed from the citizen’s side. As long as there is limited political motivation, the citizens will probably develop a more responsible and respectful behavior towards the public policy. The proposed approach increases sharing and participation within the users’ communities and guides them to respect governments and their politics.

KEY TERMS AND DEFINITIONS

Cloud Computing: A platform for delivering electronic services from any place and in any time.

Community Cloud: A community operated platform for delivering electronic services from any place and in any time.

Government as a Service: Virtual governance that service platform in which both software and data are located on the cloud.

Online Community: A community that operates through a public or private electronic network.

Semantic Web: A conversion of the World Wide Web that stores information in webpages which is readable from other computers and will be used for the understanding of the webpage's content.

Virtual Organization: An organization that operates through a public or private electronic network.

Web 2.0: The inclusion of social elements on the World Wide Web.

Clouds of Quantum Machines

Nilo Sylvio Serpa

Universidade Paulista, Brazil

INTRODUCTION

This work is a continuation of studies started at 2014. Since then, I improved some ideas about theoretical quantum machines interacting in cloud operation, as well as enhancements on the concept of quantum entanglement itself. Some recent works have been added to the original references, although the classic treatises remain in effect, given the slowness with which the subject progresses.

As we know, one of the great challenges in quantum computing is how to preserve quantum entanglement, since microphysical systems are extremely sensitive to external disturbances. It is one of my aims to show a way to minimize this problem. Moreover, a quantum orchestration metalanguage is introduced into a first schematic representation of the operation of a quantum cloud aiming to optimize further constructions of quantum algorithms. While it is essential that the reader becomes familiar with quantum mechanics, some parts of my first work are reproduced here in order to reduce the effort to understand the subject.

BACKGROUND: SERVICES AND CLOUDS IN A CONTEMPORARY APPROACH

Services are cybernetic replicas of human practices, being evoked by well-established environmental motivations. In turn, SOA is an architecture that integrates in a standard manner several service units, each of them sending their features as sets of tasks over the network. Only service interfaces are exposed to consumers as exported methods (Nakamura *et al.*, 2004). Therefore, when services

are requested, SOA seeks the best responses to those environmental motivations according to the internal logic of each service. In particular, this architecture is now strongly linked to the theme of “enterprise application integration” (EAI) in contexts where legacy applications already established are performed on different platforms.

The literature on SOA comprises several milestone contributions as the works of Nakamura *et al.* (2004), Erl (2005), Anderson & Ciruli (2006), Natis (2007), Sha (2007) and, markedly, Frenken *et al.* (2008) about device-level service deployment. On this latter subject, it is noteworthy that, in the process of architectural development, devices which access legacy applications are created and interact using a protocol defined by the system. In turn, the system returns the aggregated information from the various legacy applications, preferably without any additional code. The architectural development also takes care of the service interface, prescribing the information required to access the competences of that. It is worth remembering that the existence of interfaces and descriptions of accessibility is *sine qua non* for the implementation of SOA. More recent works show the state-of-art in services orchestration (MEF Forum, 2015; Lemos *et al.*, 2015).

In SOA projects, the so-called Enterprise Service Bus (ESB) is thought to be the main component of the infrastructure layer. It is the mediator between provider and service consumers, and its responsibility is to provide integration and interoperability between different systems. Embedded in this responsibility is also the mission of cleaning the databases by a service that tracks and recognizes all of the systems which shall be linked. Connectors are created in the databases feeding a new datawarehouse completely normal-

DOI: 10.4018/978-1-5225-2255-3.ch091

ized, such that any updates made on the original basis are automatically computed and reflected in the standardized repository.

As a logical consequence of the advent of the Internet and the concept of SOA, we can say that cloud computing is a cybernetic implementation by which all IT resources (hardware, software, networking, storage, etc.) are provided as services on-demand to consumers via Internet, remaining managed to ensure fast delivery, high availability, security and quality. In short, cloud computing is a model of computation by which those IT resources are randomly dispersed in the network, being offered as services paid as they are consumed. Although this subject promotes a lot of controversy about information security, everything suggests that the process of agglomeration of servers in clouds is irreversible.

Cloud computing and SOA have contributed significantly with one another and should remain so for a long time. In the words of David Linthicum, “SOA can be used as a key technology-enabling approach to leverage cloud computing” (Linthicum, 2009). Thus, the use of SOA can be galvanized by the cloud structure, since it allows on-demand delivery beyond the limitations imposed by the firewall constraints of the enterprise environment. A cloud computing system, whether formed by quantum machines and evolving to the point of hosting thousands or millions of servers, leads to a probabilistic approach of the states of each component as well as the states of information. As in quantum mechanics, where the physical position of a particle is random-dispersed until the intervention of an observer, the information is “nowhere”, and, at the same time, “everywhere” until an objective request is done. This probabilistic approach of the cyber states of the cloud and their components is consistent with a vector representation in Hilbert space, just as the latter is used in quantum mechanics. With respect to the theoretical foundations and not on the scale of physical phenomena, the above conceptual and formal analogy improves the ways to understand

the behavior of a “quantum cloud”, and, reversely, our understanding of quantum physics and its paradigmatic importance to modern informatics, a fact that certainly contributes to future advances in the field of cybernetics. In the next sections I will explain the representative basis to build quantum clouds, discussing the main outcomes expected from such a technology.

PROBABILITY AND SYMMETRY IN QUANTUM MECHANICS

The concept of physical probability was really born with the adventure of quantum mechanics, even though in the core of this discipline it has been treated systematically as the expression of the inexact knowledge.

The focal point was to interpret the so called wave function ψ — the amplitude of the wave itself — and Max Born was the prime to achieve it. As we know, ψ is solution of the famous wave equation for one particle with mass m , due to Schrödinger

$$-\frac{\hbar^2}{2m}\nabla^2\psi + V\psi = i\hbar\frac{\partial\psi}{\partial t}, \quad (1)$$

where V is the potential and $\hbar$ is the Planck constant divided by 2π . The functions ψ are in general complex. The connection of such quantities to the “real” world (or, which came to be the same, the acquirement of quantities called “observables”) is represented by means of operations such as $\psi_i^*\psi_i$, where ψ_i^* is the complex conjugate of ψ_i . It prays a fundamental postulate of quantum mechanics that $|\psi(r,t)|^2 = \psi_i^*\psi_i$ is the density of the probability $P(r,t)$ for a particle of mass m to be found at the point r , on time t . Therefore, the likelihood to locate the particle inside an infinitesimal volumn of space τ on that time t is

$$|\psi(r, t)|^2 d\tau. \quad (2)$$

Only in the case of one particle, the configuration space of the function ψ is isomorphic to the tridimensional space of positions. For two particles, for example, the wave function of the system ($\psi(r_1, r_2)$) is defined in a configuration space of six dimensions.

Since the summation of the probabilities referring to events that are mutually exclusive is 1, it follows

$$\int P(r, t) d\tau = \int |\psi(r, t)|^2 d\tau = 1. \quad (3)$$

Once ψ is not an observable quantity, there is a certain freedom of choice of its form. Besides, the solutions of linear equations, like Schrödinger's equation, may be multiplied by complex numbers, remaining solutions, so that expression (3) turns possible to choose a correct amplitude factor. The point of view of the physical interpretation sustains that the probability $P(r, t)$ is in fact the reflection of an objective property of the "particle", which is that the possible eigenvalues coexist as propensions in a reference class until a macroscopic intervention (a measurement) takes place. Such intervention changes drastically the original reference class. Let us take a system with states $|\psi\rangle$ and $|\psi'\rangle$ respectively before and after the experimental intervention. It's clear that the function ψ is somewhat conjectural here, but, for all theoretical purposes, is ever possible to think this function as a set of states reducible to a unique state (the reduction of the "wave packet"). We must consider the set $|\psi\rangle$ while not specified any function ψ by the apparatus of measurement, in such manner that we have two distinct instances of the reality, one before and other after the observation.

Quantum measurements are represented by a collection $\{\hat{\phi}_\lambda\}$ of operators that act upon the

phase space of the system under observation. The subindex λ labels the possible results of measurement. Let us suppose that the system is in the initial state $|\cdot\rangle$. The probability for a certain state λ after the measurement is,

$$P(\lambda) = \langle \cdot | \hat{\phi}_\lambda^\dagger \hat{\phi}_\lambda | \cdot \rangle, \quad (4)$$

where $\hat{\phi}_\lambda^\dagger$ is the conjugate transposed of $\hat{\phi}_\lambda$,

$$\langle \cdot | \cdot \rangle = 1$$

and

$$\hat{\phi}_\lambda^\dagger \hat{\phi}_\lambda = 1.$$

This is what mathematically signifies to be a normalized state in quantum mechanics. Now, let $|\mu_1\rangle, |\mu_2\rangle, |\mu_3\rangle, \dots, |\mu_q\rangle$ be an orthonormal base. Thus,

$$\hat{\phi}_\lambda = |\mu\rangle \langle \mu| \quad (5)$$

is a quantum measurement. The intervention of the apparatus modifies the state of the system to

$$\frac{\hat{\phi}_\lambda |\cdot\rangle}{(\langle \cdot | \hat{\phi}_\lambda^\dagger \hat{\phi}_\lambda | \cdot \rangle)^{1/2}} = |\cdot'\rangle; \quad (6)$$

$$\frac{|\mu\rangle \langle \mu | \cdot \rangle}{(\langle \cdot | \hat{\phi}_\lambda^\dagger \hat{\phi}_\lambda | \cdot \rangle)^{1/2}} = |\cdot'\rangle; \quad (7)$$

$$\frac{|\mu\rangle \langle \mu | \cdot \rangle}{(\langle \cdot | \langle \mu | \mu \rangle | \mu \rangle \langle \mu | \cdot \rangle)^{1/2}} = |\cdot'\rangle; \quad (8)$$

$$\frac{|\mu\rangle\langle\mu|\cdots\rangle}{(\langle\cdots|\mu\rangle\langle\mu|\cdots\rangle)^{1/2}} = |\cdots\rangle; \quad (9)$$

$$\frac{|\mu\rangle\langle\mu|\cdots\rangle}{|\langle\mu|\cdots\rangle|} = |\cdots\rangle. \quad (10)$$

THE VECTORIAL BACKBONE OF QUANTUM MECHANICS

The vector space of quantum mechanics is a Hilbert space, that is, an orthonormal vector space in which

1. The vector components are complex scalars;
2. The scalar product satisfies $\langle\psi|\psi\rangle > 0$ for $|\psi\rangle \neq 0$, otherwise $\langle\psi|\psi\rangle = 0$;
3. If a and b are complex scalars, then

$$\langle\chi|a\psi_1 + b\psi_2\rangle = a\langle\chi|\psi_1\rangle + b\langle\chi|\psi_2\rangle;$$

4. The space is complete in the norm $\|\psi\| = \sqrt{\langle\psi|\psi\rangle}$.

Finally, the implementation of symmetries in generalized quantum mechanical coordinates¹ may be represented by a unitary operator in the Hilbert space, so that,

$$\mathcal{U}^\dagger \mathcal{U} = 1, \quad [H, \mathcal{U}] = 0;$$

for the groundstate of the Hamiltonian

$$H = -\frac{\hbar^2}{2m} \nabla^2 + V,$$

$$\mathcal{U}|\psi_0\rangle = |\psi_0\rangle; \text{ (this is not so obvious!)}$$

$$H|\psi_0\rangle = E_0|\psi_0\rangle;$$

$$\mathcal{U}H|\psi_0\rangle = E_0(\mathcal{U}|\psi_0\rangle).$$

In fact, accordingly von Neumann theorem, a coordinate transformation that corresponds to a symmetry of the Hamiltonian let invariant the canonical commutation relations of the system and (here is the power of the theorem) may always be implemented by an unitary manner in the Hilbert space of the states. So,

$$\hat{q}'_i = \mathcal{U}(S)\hat{q}_i\mathcal{U}^\dagger(S) = S_{ij}\hat{q}_j;$$

$$\mathcal{U}(S) = e^{i\omega\hat{O}},$$

where $\hat{O}$ is an operator that defines a motion constant (thereby furnishing good quantum numbers for the states of the system) so that $\hat{O}^\dagger = \hat{O}$, and ω is the set of parameters defining the matrix S .

Of course, as an effect of the macroscopic intervention, μ shows some classic traces inherited from the apparatus. But quantum mechanics says nothing about the world out of the experiment. Also, it is important to clarify that it is not always possible to carry out a complete and decisive experiment in this area. For instance, with respect to gravity, an approach by quantum field theory would need 1) an understandable model of gravitation accordingly some quantization algorithm applied to general relativity, which seems little bearing, and 2) an experimental frame able to reproduce the physical conditions under which the hypothetical quantum nature of gravity may come about, such as in a black hole singularity. In fact, one reason to brush aside an experimental program in this way is the difficulty of formulating quantum theory in a cosmological context in which the observers must be part of the system. Although it appears out of the blue, we may suppose there is a real messenger of gravity and imagine a “metaframe” to render gravitation in a familiar figurative language with no *a priori* concerns whether the messenger and its supersym-

metric partner follow Bose or Fermi statistics beneath lab apparatus. This was my proposal: a supersymmetric meta-field theory on gravity (Serpa, 2015). So, I define meta-field theory as a theory that introduces a supersymmetric metaframe to describe fields as sets of particular transformations between two types of entities, the supersymmetric partners in focus.

As in the supersymmetric meta-field theory, it is possible to build a similar metaframe to describe cloud computing in its continuous process of increasing complexity. I will try, so much as possible, to refine the presentation of the formalism in order to avoid time lost with unclear notations and conventions.

THE QUANTUM BIT

The quantum bit, or qubit, is the quantum tile of information and differs from the classical bit by the fact that it is generally given in a superposition of two basic states, e. g., $|0\rangle$ and $|1\rangle$, so that the Dirac ket of the time-dependent state-function of a qubit is denoted by

$$|\Psi(t)\rangle = c_0(t)|0\rangle + c_1(t)|1\rangle,$$

where $c_0(t)$ and $c_1(t)$ are complex time functions. The binary assigned to the basic states are associated with discrete values assumed by physical degrees of freedom of elementary particles, such as the spin. The qubit state fulfills equation (1) in such manner that the Hamiltonian operator takes the form

$$H(t) = h_{00}(t)|0\rangle\langle 0| + h_{01}(t)|0\rangle\langle 1| + h_{10}(t)|1\rangle\langle 0| + h_{11}(t)|1\rangle\langle 1|.$$

Sometimes it is useful to rewrite Schrödinger's equation in matrix formalism as

$$i\hbar \begin{pmatrix} \dot{c}_0(t) \\ \dot{c}_1(t) \end{pmatrix} = \begin{pmatrix} h_{00}(t) & h_{01}(t) \\ h_{10}(t) & h_{11}(t) \end{pmatrix} \begin{pmatrix} c_0(t) \\ c_1(t) \end{pmatrix}.$$

Last, normalization condition applies

$$|c_0|^2 + |c_1|^2 = 1.$$

QUANTUM TELEPORTATION

Quantum teleportation is a very different conception of their science fiction counterparts. Since the nineties authors have studied the subject in theoretical and experimental approaches (Deutsch & Jozsa, 1992; Braunstein, 1996; Bouwmeester, 1997; Zhang *et al.*, 2002; Bowen, 2003).

The concept of quantum teleportation and the so-called quantum entanglement form the basis of cloud computing as conceived here. The latter is one of the biggest sources of confusion in science, since quantum entanglement became a paradox in quantum theory because of its conflict with causality. Two quantum objects are said entangled if they are linked in such manner that their behaviors are bonded never minding how much distant they are from one another. I will try to explain the central idea in the cloud context with a maximum of formal consistence on the previous sections.

We start with two state functions to be entangled at server A , $|\Psi_{\uparrow}\rangle_A$ and $|\Psi_{\downarrow}\rangle_A$. The entanglement is given by the instruction 0 (I_0) of the experiment

$$I_0 : |\Psi_{\uparrow}\rangle_A \# |\Psi_{\downarrow}\rangle_A \Rightarrow |\Psi_{(\uparrow\downarrow)(\uparrow\downarrow)}\rangle_A. \quad (11)$$

The two state functions are now non-causally correlated. After the entanglement, we apply by instruction 1 (I_1) a classical procedure P_1 to carry the second entangled state function on server B , that is,

$$I_1 : P_1 \left| \Psi_{(\uparrow\downarrow)(\uparrow\downarrow)} \right\rangle_A \stackrel{\circ}{=} \left| \Psi_{(\uparrow\downarrow)(\uparrow\downarrow)} \right\rangle_A (-) \left| \Psi_{(\uparrow\downarrow)} \right\rangle_A \equiv \left| \Psi_{(\uparrow\downarrow)} \right\rangle_B.$$

Now we perform a measurement $|M\rangle$ in server A on the combined state which we gain putting $\left| \Psi_{(\uparrow\downarrow)} \right\rangle_A$ in contact with the unknown state function $|\chi\rangle$. Having done this interaction, server A transmits to server B , through a classical channel reachable by procedure P_2 , a complete description of the results of the quantum measurement on $|\chi\rangle \left| \Psi_{(\uparrow\downarrow)} \right\rangle_A$ in order to enable server B to perform certain linear transformation $|\delta\rangle$ on $\left| \Psi_{(\uparrow\downarrow)} \right\rangle_B$; in fact, the measurement described annihilates $|\chi\rangle$, but the linear transformation $|\delta\rangle$ rebuilds the latter at server B from $\left| \Psi_{(\uparrow\downarrow)} \right\rangle_B$, so that by instruction 2 (I_2)

$$I_2 : P_2 |M\rangle |\chi\rangle \left| \Psi_{(\uparrow\downarrow)} \right\rangle_A \stackrel{\circ}{=} |\delta\rangle \left| \Psi_{(\uparrow\downarrow)} \right\rangle_B \equiv |\chi\rangle.$$

This is what we call teleportation of the state $|\chi\rangle$ from server A to server B . Quantum teleportation refers to the “blind” teleport of the state of a quantum system about which there was no information. The measurement does not provide any information from the state function $|\chi\rangle$. All of the quantum state information is passed by the non-causal link between the entangled states $\left| \Psi_{(\uparrow\downarrow)} \right\rangle_A$ and $\left| \Psi_{(\uparrow\downarrow)} \right\rangle_B$. The main consequence of the process is the annihilation of the initial quantum state at server A rebuilt at server B . It must be understood that it is the quantum states which are destroyed and recreated in the teleportation process, and not material components. Thereby, cloning is an impossible operation in quantum physics; we simply can generate an almost-perfect

replica of the original destroyed after teleportation. It is also important to remember that quantum information within a state function is available only as probabilities or, as we commonly say, expectation values.

ENTANGLEMENT: THE PICTURES ON THE POOL

It was pointed that quantum processing was born from “purely philosophically motivated questions” (Walther, 2006) on non-locality and completeness of quantum mechanics fomented mainly by Einstein from his collaborative work with Podolsky and Rosen in 1935. In fact, as once observed, it was Einstein whom restored in modern science the Cartesian metaphysical sense of philosophy, turning physics into a real theory of knowledge (Charon, 1967). This important note remembers to us that philosophy will always be present in the process of creation. It is precisely its absence that determines little creativity that prevails today in all fields. Thus, to understand what is entanglement it will be necessary a reflective process of reconstruction of the conceptual foundations of physics, which will lead to a comprehensive review of the applicability of the notion of causality.

The main controversies of quantum mechanics ever resided in the difficulty of the human mind to separate the physical fact from its perception or representation. Indeed we always work with our perceptions; we took from them the full potential of human development and survival offered, creating representations for all we observe. There was a time when I was a follower of a kind of fruitless and paralyzing materialism that insisted to reify the world. Later, influenced by some physicists adepts of the operationalism, I came also to sympathize with the dresser and foolish idea that the only thing that matters is the calculation and not the ultimate nature of things. Thanks to my growing interest in quantum computing, I could deepen those controversial discussions and reach my own conclusions about them. Of course, long before the

seventies there were eloquent speeches from the great thinkers of modern physics. Weizsäcker, for instance, in the Spanish version of 1974: “*El átomo no es inmediatamente perceptible para nuestros sentidos, y cualquier experimento lleva sólo una determinada propiedad del átomo al ámbito de una perceptibilidad mediata*”² (Weizsäcker, 1974). But that was still little; not just to observe a predicate and describe it by means of classical concepts. It was necessary a phenomenal texture made by the experimental apparatus from which one could then extract useful measurements (information). In this it would lie a deepening of the famous complementarity of Bohr: the ultimate hidden object and its accessible and inseparable image.

Inspired by those philosophical texts from the first half of the twentieth century and early second half, I could refine my ideas and reach an understanding which I consider acceptable, although limited by the nature of human thought. Now I believe that the understanding of the quantum entanglement, one of the most intriguing phenomena of the quantum world, rises, for happiness of the philosophers, in a reflection on the edge of a pool. One summer night, I sat in a chair right in front of a lighted lamp whose flickering light was reflected in the pool. The image of the lamp stretched like a rubber with the ripples of the water and sometimes came to double or even to quintuple depending on the swings of the water. Both, the lamp and its images in water, are real, belonging to the world of mater and perceptions. But imagine that we could not see the lamp, only their images reflected in the water. We would think that two objects born of a unique (duplicate picture) would be irrevocably united, although separated; any change in one of them would “cause” an instantaneous change in the other. With respect to the quantum world is passing up something similar. We have no direct access to the ultimate reality (as the hidden lamp), only to the images produced by our experiments. What we see are the “pictures in the pool” and these are as real as the object that produced them. Clearly, these images carry information from the ultimate object, which makes them tractable to

control. Instead of using the ultimate object we use them with all their informational potential. This potential is the base of the teleport process, since we teleport physical states, not matter in itself. In short, the quantum world is so light and sensible to our presence that it would be impossible to get direct benefits from their objects. All we can do is work with “pools”. As Weizsäcker said: “*Todo experimento es un acto material que es simultáneamente um acto de percepción*”³ (Weizsäcker, 1974).

To get a slight idea of quantum entanglement we consider the process of creation and destruction of a pair of quantum bits called “pair of Einstein, Podolsky and Rosen” (EPR pair). So, let us suppose a quantum bit in a zero-state,

$$|\Psi_1\rangle = 1|0\rangle + 0|1\rangle = |0\rangle.$$

Now, let us take the Hadamard matrix H_2

$$H_2 = \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

and

$$U_2 = \frac{1}{\sqrt{2}} H_2.$$

We make

$$\begin{aligned} |\Psi'_1\rangle &= U_2 |\Psi_1\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \\ &= \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \frac{1}{\sqrt{2}} |0\rangle + \frac{1}{\sqrt{2}} |1\rangle. \end{aligned}$$

Also we take another quantum bit in zero-state

$$|\Psi_2\rangle = 1|0\rangle + 0|1\rangle = |0\rangle.$$

Performing a tensor product between $|\Psi'_1\rangle$ and $|\Psi_2\rangle$ we gain

$$|\Psi'_1\rangle \otimes |\Psi_2\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \end{pmatrix} = \frac{1}{\sqrt{2}} |00\rangle + 0 |01\rangle + \frac{1}{\sqrt{2}} |10\rangle + 0 |11\rangle.$$

It is convenient to define certain unitary transformation, called “control NOT-gate” (CNot). Using Pauli matrices

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

we may write

$$CNot = \frac{1 + \sigma_z}{2} \otimes 1 + \frac{1 - \sigma_z}{2} \otimes \sigma_x =$$

$$= \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \text{ so that}$$

$$CNot |\Psi'_1 \Psi_2\rangle = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \end{pmatrix} =$$

$$= \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix} = \frac{1}{\sqrt{2}} |00\rangle + \frac{1}{\sqrt{2}} |11\rangle. \quad (12)$$

The point is that for entangled states, as expressed in the above result, decomposition does not hold, that is,

$$\left\{ \#(\varphi_1, \varphi_2) / \varphi_1 \otimes \varphi_2 = \frac{1}{\sqrt{2}} |00\rangle + \frac{1}{\sqrt{2}} |11\rangle \right\}.$$

The very strangeness of entanglement may be explained taking two distinct moments of experimental intervention. Just prior the *CNot* transformation we perform a measurement to obtain the probability of $|0\rangle$. The measurement operator is

$$M_0 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Before the *CNot* transformation the system is in state

$$|\Psi'_1 \Psi_2\rangle = \frac{1}{\sqrt{2}} |00\rangle + 0 |01\rangle + \frac{1}{\sqrt{2}} |10\rangle + 0 |11\rangle.$$

Therefore,

$$\begin{aligned} p(0) &= \langle \Psi'_1 \Psi_2 | M_0^\dagger M_0 | \Psi'_1 \Psi_2 \rangle = \\ &= \langle \Psi'_1 \Psi_2 | M_0 | \Psi'_1 \Psi_2 \rangle = \end{aligned}$$

$$= \frac{1}{\sqrt{2}} (1, 0, 1, 0) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \end{pmatrix} =$$

$$= \left(\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}}, 0 \right) \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \\ \frac{1}{\sqrt{2}} \\ 0 \end{pmatrix} = 1.$$

After measurement we get for the state of the system

$$\frac{M_0 |\Psi_1 \Psi_2\rangle}{\sqrt{\langle \Psi_1 \Psi_2 | M_0^\dagger M_0 | \Psi_1 \Psi_2 \rangle}} = \frac{\begin{pmatrix} \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} \\ 0 \\ 0 \end{pmatrix}}{1} = |\Psi_1 \Psi_2\rangle. \quad (13)$$

We see that measurement had no influence on the first quantum bit that remains in a superposition of $|0\rangle$ and $|1\rangle$. This is not the case when we perform the same measurement just after the *CNot* application. Now we start from

$$\Psi_3 = \frac{1}{\sqrt{2}} |00\rangle + \frac{1}{\sqrt{2}} |11\rangle.$$

Let us compute the probability of $|0\rangle$ by means of

$$p(0) = \langle \Psi_3 | M_0^\dagger M_0 | \Psi_3 \rangle = \langle \Psi_3 | M_0 | \Psi_3 \rangle =$$

$$= \frac{1}{\sqrt{2}} (1, 0, 0, 1) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix} = \frac{1}{2}.$$

Thereby, probability of $|0\rangle$ was changed to $1/2$. After measurement, the state vector of the system took the form

$$\frac{M_0 |\Psi_3\rangle}{\sqrt{\langle \Psi_3 | M_0^\dagger M_0 | \Psi_3 \rangle}} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \times$$

$$\times \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \\ 0 \\ \frac{1}{\sqrt{2}} \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} \frac{1}{\sqrt{2}} \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = |00\rangle.$$

This is somewhat astonishing. Measuring one quantum bit we modify the probabilities of the other quantum bits of the system. However, as strange as the phenomenon is, the role of science is only to describe what happens, leaving aside ontological speculations about the “why” of the things being as they are.

MAIN FOCUS

Operators in quantum mechanics commonly provide representations of experimental interventions. But this does not mean that reality is determined by the observer. In fact, the experiment is just a physical intervention rationally controlled similar to the natural physical interventions occurring at random in the interactions between systems. An-

other important consideration to be made is about the clear representational role that mathematical constructs which serve to quantum mechanics must have, for example, the construct “quantum gate”. Accordingly McMahon (2008),

A gate can be thought of as an abstraction that represents information processing. [...] In a quantum computer, information is also processed using gates, but in this case the “gates” are unitary operations. Since quantum gates are just unitary operators, we’ll often go back and forth between the words gate and operator --- so keep in mind they mean the same thing in this context. (McMahon, 2008).

Then, we may say that quantum gates are connectors that allow us to building quantum circuits. They act upon quantum bits; thus, generalizing the concept, we may think of them as formal representations of particular circumstances imposed by the environment or the observer, never mind- ing whether they are controlled or not. They are operators of certain type acting on quantum bits to do something, that is, to produce some specific quantum configuration.

THINKING ABOUT NON-UNITARY OPERATIONS EMBEDDED IN ENTANGLED STATES: DOES IT MAKE SENSE?

In its current formal representation, quantum computation deals only with quantum gate operations which are necessarily unitary, a fact that turns difficult or even impossible to solve central problems such as decoherence and feasibility of measurements in the middle of the computation. From my theoretical background, the restriction to unitary gates and pure quantum states seems very arbitrary. Quantum gates can perfectly represent general quantum operations, not exclusively unitary, providing more flexibility and facility to building algorithms. Unitary operations can,

at best, be elected to represent the evolution of a quantum system under observational control, but not necessarily to represent quantum systems free of human intervention. Many works were performed on quantum gates (Barenco et al., 1995; Raussendorf & Briegel, 2000; Wang et al., 2001), so that the reader can deepen his particular search as desired.

What I want to show is that, given two entangled quantum bits, it is not possible to know whether the entanglement arose from the interference of some non-unitary action on a given quantum bit in a pure initial state. This means that quantum bits separated by large distances may carry effects of primary out-of-measurement processes that originated them. So, could we embed quantum states with these non-unitary actions, that is, these out-of-measurement transformation rules? If so, how would be the protocol for that?

First of all, as already suggested, I assume that certain operators reflect environmental conditions that favor the creation of new qubits from a primary qubit. In my former works, I developed the math entity named “progenitor” as the Kronecker operator to obtain two entangled qubits. According to my considerations on Bohr’s philosophical thinking, there must be an abstract quantum physical description of the natural process that leads to entangled qubits interacting through a quantum channel. I assume that if what connects two entangled qubits far from one another is a non-classical channel, that is, no transaction between entangled qubits occurs in common spacetime, so what triggered such a connection is an imaginary “operation”. So, the transfer of information in a quantum system, based on the non-classic connection between qubits, is holding through an imaginary “operation” like

$$\hat{G} := \frac{1}{\sqrt{2}} \begin{pmatrix} \mathbf{i} & -\mathbf{i} \\ 0 & -\mathbf{i} \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -\mathbf{i} \\ 0 & -\mathbf{i} \end{pmatrix},$$

where $\mathbf{i} = \sqrt{-1}$, and

$$\begin{pmatrix} \mathbf{i} & -\mathbf{i} \\ 0 & -\mathbf{i} \end{pmatrix} \begin{pmatrix} -\mathbf{i} & \mathbf{i} \\ 0 & \mathbf{i} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

The object

$$\frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -\mathbf{i} \\ 0 & -\mathbf{i} \end{pmatrix}$$

is the progenitor, that is, an operator which acting on a qubit by a Kronecker product on the left gives one two-qubit system in a certain configuration such that, under a control gate, it outputs a pair of entangled qubits. The Kronecker product protocol (KP) comes

$$\frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -\mathbf{i} \\ 0 & -\mathbf{i} \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ -\mathbf{i} \\ 0 \\ 0 \\ 0 \\ -\mathbf{i} \\ 0 \end{pmatrix}. \quad (14)$$

Applying the correct imaginary gate, it follows

$$\begin{pmatrix} \mathbf{i} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \mathbf{i} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \mathbf{i} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \mathbf{i} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \mathbf{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \mathbf{i} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \mathbf{i} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \mathbf{i} \end{pmatrix} \times \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ -\mathbf{i} \\ 0 \\ 0 \\ 0 \\ -\mathbf{i} \\ 0 \end{pmatrix} = \frac{-\mathbf{i}}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ \mathbf{i} \\ 0 \\ 0 \\ 0 \\ \mathbf{i} \\ 0 \end{pmatrix} =$$

$$= \frac{1}{\sqrt{2}} |11\rangle + \frac{1}{\sqrt{2}} |00\rangle. \quad (15)$$

The reader must remember that tensor product warrants the permanence of the superposition principle, i.e., there is a way to have a little of the $\hat{G}$ -operator and a little of the original quantum state in the final state.

The advantage of this approach is the presumption of a genuine quantum channel through which imaginary transformations occur, even though we do not know the dynamic essence of the non-local phenomenon; so, the imaginary operations are the logical quantum channel paths (not physical paths in spacetime).

PRESERVING QUANTUM ENTANGLEMENT

The question is not so much of mathematical theorems but appropriate representations for the physical phenomena examined here. Thus, all my effort was directed to set representations that can be implemented in quantum algorithms to solve or minimize decoherence problems.

The quantum world is very difficult to understand because of the lack of realistic correspondence with Euclidian world. But, if we open our minds and enlarge common geometry to imagine the geometry of an object with no extension we shall be very close to the language we need to describe quantum mechanical facts in quantum computing. For the sake of simplicity, we could call “point” any indivisible structure, not uniquely the point of geometry. Thus, two entangled particles would constitute a “point” in which refers their interactions. However, this point was called “tapestry” in my quantum language. It may sound strange to call “tapestry” an entity with no extension, but this is intentional. A tapestry is understood from the onefold coverage provided by unique progenitor tensor product on one qubit. This is like to define the element of a wool rug, the minimal knot that begins a complete Persian tapestry. Thereby, one simple knot is in fact a tapestry of one element.

A fundamental issue about entanglement is that, no matter how far apart two entangled particles are from one another, what happens to one brings instantaneous response from the other. I sustain that if we use the particle image of matter, it is impossible to conceive the phenomenon of quantum entanglement, since what affects the particle can not propagate instantaneously to another particle. On the other hand, if we think about a continuous entity as a tapestry not made up by parts, then it is easy to see much more; to have no parts means to be indivisible in the space of configuration. In fact, two entangled particles constitute a physical *monad* as in the metaphysical Leibinizian sense. What is really missing is a rational form of expression suitable for such a phenomenon, both mathematically as literarily. We can well conceive the quantum *monad* as an imaginary tapestry of one element, cohesive, indivisible and intractable by common sense.

Our tapestry is an imaginary quantumfold, that is, a onefold that only exists in quantum descriptions of nature. From this quantumfold we may obtain an imaginary representation of entangled states by tensor operations applied on it. As the quantumfold is not geometrically thinkable because it is not composed by parts, it is covered, as I said, by unique progenitor tensor product to one qubit. To extract entangled states from this coverage, that is, to obtain real descriptions of states not separable from superposition principle, we logically need one imaginary gate, the only to transform (that is, to Wick-rotate) representations of imaginary objects into real ones. This gate builds a bridge between the two representations. So, let us take an important definition.

Definition 1: A tapestry $\mathbb{T}$ is a map that carries a pair progenitor-cum-qubit $(\xi^\dagger, \psi^\pm)$ on a column vector $\mathbb{I}$ with entries $(0, -\mathbf{1})$ by a Kronecker product $\langle\langle \dots, \dots \rangle\rangle$, so that

$$\mathbb{T} : \langle\langle \xi^\dagger, \psi^\pm \rangle\rangle \rightarrow \mathbb{I}_{(0, -\mathbf{1})}.$$

This approaching is derived from Serpa's proposal on Wick-rotations (Serpa, 2015). In some sense, tapestry is the generalized geometrical *locus* of qubit transformations that lead to entanglements.

Definition 2: A quantum channel is a manifold built by the connected sum of two or more tapestries such that the canonical representation of each tapestry is a word as

$$\Gamma_1 \Gamma_2 \dots \Gamma_g \Lambda_1 \Lambda_2 \dots \Lambda_h = 1,$$

meaning that the tapestry has *genus* g and h holes.

CONNECTED TAPESTRIES OVER SERVERS IN CLOUD

But not everything is perfect, since the phenomenon of decoherence — the loss of entanglement by environmental interferences — haunts quantum computing labs and brings puzzles to theorists. The problem of decoherence tantalizes scientists since long ago. However, it was demonstrated that the existence of quasiparticle excitations named non-Abelian anyons, neither classified as bosons nor fermions, is related to certain topological configurations that make immune to local decoherence the quantum information stored in such configurations (Sarma, *et al.*, 2006). Also it was reported recently what would be the first experimental demonstration of a loss resilient entanglement-based protocol, probing that, in some circumstances, it's possible to preserve properties acquired by qubits at first in entangled states (Zhang, 2013). These findings encourage theoretical investigations, including progenitor's protocol. According to the last, when a pair of qubits is produced by progenitor's action on a qubit, the imaginary tensor “operation” is somewhat “memorable” inside the generated pair in

tapestry. As we know, tensor product retains a little of the progenitor and a little of the original quantum state in the final state. To understand exactly where I want to go, let us consider the concept of measurement from the point of view of quantum mechanics.

Following von Neumann, we say that a consistent description of the measurement process in quantum physics must consider the interaction between the quantum system under observation and the quantum measurement apparatus (von Neumann, 1932). Thereby, a measurement is an intervention described by a unitary transformation that evolves the initial global state of the combined system. In this sense, the application of a certain controlled-gate builds a fact from what really happens. From the point of view of the model presented here, quantum entanglement precedes every physical measurement operation; two qubits are said entangled if they result of the transformation of a single qubit via progenitor, such that there must be at least one controlled-gate (a Wick-rotation matrix) capable of translating this entanglement as mathematically associated with an observable, albeit indirectly. The proposed protocol establishes the mathematical design of two entangled qubits from one qubit and one progenitor instead of two former qubits. Theoretically, from the notions of tapestry, imaginary quantum channel and progenitor it is possible to reduce the loss of the amount of entanglement. Now we take the Kronecker protocol (14), from which we have the tapestry representation of entangled states

$$KP|10\rangle = 0|01\rangle + 0|01\rangle + 0|11\rangle + 0|11\rangle + \\ + 0|00\rangle + 0|10\rangle - \frac{\hbar}{\sqrt{2}}|00\rangle - \frac{\hbar}{\sqrt{2}}|10\rangle.$$

Relating the terms of last expression with the formalism of surface topology, we can imagine an algorithm that converts this representation into a string (or word) such that in server *A* we read

$$|iI\rangle_A = aacbbdef$$

with

$$\begin{aligned} a &:= 0|01\rangle; \\ c &:= 0|11\rangle; \\ b &:= 0|00\rangle; \\ d &:= 0|10\rangle; \\ e &:= -\hbar/\sqrt{2}|00\rangle; \\ f &:= -\hbar/\sqrt{2}|10\rangle. \end{aligned}$$

We can make $bdef \rightarrow b$, so that canonical representation gives

$$aacbb = 1,$$

which is a Klein bottle formed by two cross caps (aa, cc) and a hole (b) (see Figure 1).

Clearly, the topology shall depend on the initial number of entangled qubits. It is obvious that cyclic order is not important to identify the topology, but once determined this latter, the cyclic order operates as a part of the signature of the entanglement itself; we may fix the total additional information about the implicit manifold, including that signature, to be transmitted by a classical channel to server *B* into a complete topological information-state packet coupled to the qubit, so that we may ensure high efficiency and fidelity repairing entanglement. The number

Figure 1. Topological planar model of $KP|10\rangle$

of possible anagrams (signatures) from a word in which there is repetition is given by

$$P_n^{(q_1, q_2, q_3 \dots)} = \frac{n!}{q_1! \cdot q_2! \cdot q_3! \dots},$$

where $q_1, q_2, q_3 \dots$ are the numbers of times that repeated letters appear in the word. For the case of Klein bottle,

$$P_5^{(2,2)} = \frac{5!}{2!2!} = 30.$$

Thus, there are 30 possible signatures for the Klein bottle.

That information-state packet is the “memory” of entanglement and serves to preserve it from external perturbations. The connected sum (entanglement) $|i\mathcal{I}\rangle_{A\#B}$ represents the physical connection — the quantum channel — between the qubits and is written as

$$|i\mathcal{I}\rangle_{A\#B} = a_1 a_1 c_1 c_1 b_1 a_2 c_2 c_2 b_2.$$

Then, entanglement is a quantum phenomenon in which, through the quantum channel, the two tapestries in servers A and B are connected as the two *tori* in Figure 2. All we have to do is to transmit the topological information-state associated to the Kronecker protocol from server A to server B . If noise removes entanglement between two qubits, the reapplication of the control imaginary gate (the reconstruction of the quantum channel between the qubits) in server B through a quantum circuit will restore, in thesis, the entanglement from that memorized information shared by the two qubits.

$$a_1 b_1 a_1^- b_1^- a_2 b_2 a_2^- b_2^-.$$

Figure 2. Connected sum of two tori

ORCHESTRAL METALANGUAGE

To think about quantum cloud computing is a natural consequence when we investigate the potential of quantum machines. From here, it rises a plethora of interesting subjects, including security and privacy of computation by blind quantum computing based on the transmission of individual photonic qubits (Barz *et al.*, 2012). Thus, it is a great challenge to understand the complexity of services to be orchestrated in quantum clouds.

The task of identifying and matching services is far from obvious. Potential applications of quantum mechanics in everyday life always bump into a linguistic modeling problem, a fact which greatly complicates the accurate understanding of what we want to do and what we can really do. For this reason, the structuring of an orchestral metalanguage is decisive for the correct construction of the topology of services, evidencing scalability and giving descriptive accuracy and, in the same breath, great facility of implementation of changes. In addition, as well observed by Metodi and Chong, a quantum computer of practical value must be up to storing and orchestrating a system comprising tens of millions qubits (Metodi & Chong, 2006). Therefore, that orchestral metalanguage would be an interesting tool to represent such a complex dynamics.

With respect to the above introduced metalanguage and to make it clearer, it is important to consider the idea of orchestration as referring not

only to the service composition, but also to the topology that determines the order in which the services occur in a given process. We begin by defining a functional f as a unique service for state analysis. It informs a given composite service S about the best orchestration of elementary services to be performed depending on demand and the current state of the environment or on a collection of orchestrations identified on the same basic services to be initialized in parallel, depending on the overhead consumption. There are two ways of doing work one functional on a composite service as we shall see.

The lexicon of the metalanguage, that is, its main catalogue of elementary connectors and words, is given by what we call a primitive base as follows:

Now we look at the grammar of the metalanguage, that is, the rules to combine connectors and words in such manner that we may build meaningful statements (axioms, definitions, sentences, *etc.*):

Table 1. Primitive base

S	Composite service
s	Elementary service
f	Functional
Υ	Combined with (to compose services)
$\succ$	Call forward
$\prec$	Call backward
$\prec \succ$	Parallel running
$\wedge$	Defined as
$\langle f $	Right functional
$ f \rangle$	Left functional
O^1	Orchestration in one dimension

Definition 1: It is called weak coupling the orchestration O^1 of elementary services s_i to which there is mutual communication among the orchestration component services.

Axiom 1: For any set of elementary services s_i there is at least one weak coupling O^1 on s_i , such that O^1 on s_i is an application of the topology T^1 on s_i equivalent to the composite service S^1 :

$$\left\{ \forall \{s_i\} \exists O_{\{s_i\}}^1 / O_{\{s_i\}}^1 : T^1 \{s_i\} \Leftrightarrow S^1 \right\}.$$

Definition 2: It is called agglomerate the meeting O^k of k weak couplings on the same basic services, being $k = 1, 2, 3 \dots n$ the size of the agglomerate and $O^k \Leftrightarrow S^k$.

Axiom 2: For every set of basic services s_i , there is at least one agglomerate O^k on s_i , such that O^k on s_i is an application of the topology T^k on s_i equivalent to the composite service S^k :

$$\left\{ \forall \{s_i\} \exists O_{\{s_i\}}^k / O_{\{s_i\}}^k : T^k \{s_i\} \Leftrightarrow S^k \right\}.$$

Definition 3: It is called “left” functional action the initialization of the weak coupling O^1 which has the best performance among all identified weak couplings on the same basic services.

Definition 4: It is called “right” functional action the initialization of the agglomerate O^k .

Corollary: All weak coupling O^1 is an agglomerate of dimension $k = 1$.

It must be understood that both lexicon and grammar can be enlarged as the representational complexity advances. For instance, let us take an example of a functional action at “left” and at “right”,

$$\begin{aligned}
& |f\rangle S^1 \wedge \langle s_1 \succ \langle s_2 \succ s_3 \rangle \succ \langle s_4 \succ s_5 \succ s_6 \rangle \rangle; \\
& S^4 \langle f | \wedge \left\| \begin{aligned} & \langle s_1 \succ \langle s_2 \succ s_3 \rangle \succ \langle s_4 \succ s_5 \succ s_6 \rangle \rangle \\ & \langle s_1 \succ \langle s_2 \succ s_3 \rangle \succ \langle \langle s_4 \succ s_5 \rangle \succ s_6 \rangle \rangle \\ & \langle s_1 \succ \langle s_2 \succ s_3 \rangle \succ \langle s_4 \succ s_5 \succ s_6 \rangle \rangle \\ & \langle s_1 \succ \langle s_2 \succ s_3 \rangle \succ \langle s_4 \succ \langle s_5 \succ s_6 \rangle \rangle \end{aligned} \right\|, \\
& S^4 \langle f | \wedge \left\| \begin{aligned} & O^1 \\ & O^2 \\ & O^3 \\ & O^4 \end{aligned} \right\|.
\end{aligned} \tag{16}$$

Expression (16) is called parallelism matrix and its dimension k depends primarily on the number of elementary services and the number of available qubits. It is understood that service combinations, expressed between kets, must precede external calls. Large service chains with related functions can be represented in this way, documenting all the required topologies. Considering two servers, A and B , and taking the last column-matrix, quantum teleportation of this four-dimensional agglomerate from server A to server B , by the instruction 2 from Equation 6, would be given by

$$\begin{aligned}
I_2 : P_2 |M\rangle |O^1 O^2 O^3 O^4\rangle |\Psi_{(1)}\rangle_A &= > \\
\Rightarrow |\delta\rangle |\Psi_{(1)}\rangle_B &\equiv |O^1 O^2 O^3 O^4\rangle.
\end{aligned}$$

Operating under metacomputation, B will perform the same task as server A could do, however, with no needs to repeat the process of topological analysis done by A . In server B , all topological possibilities can be used simultaneously to perform parts of a computation (service).

Figure 3 (in appendix) outlines the SOA overlay intermediating clients and quantum machines in a certain hypothetical production environment. Servers A , B and C are supercomputers originally sharing the same quantum channel. At the right of the ESB a client requests certain complex service. By means of a protocol translation hardware (PT)

located at the left of the ESB, a query is addressed to the quantum machines B and C to know whether the requested service is already available. If the answer is negative, the request is forwarded to the quantum analyzer A . Until now, all we have done took place by means of classic channels. From now on, having defined the best orchestration, the quantum analyzer teleports the state matrix to both servers B and C ; the probabilistic parallel processing begins in B and C at the same time that state matrix is destroyed at A . This diagram was inspired in a more general scheme called one-to-many teleportation. Due to entanglement, probabilities in B and C interfere with one another. The requested service results from the instantaneous “collapse” (see Figure 4 in appendix) of the copies of the state matrix into new states at PT (mathematically, this is a change of probabilistic reference class). Finally, service is really available for the client through ESB. While in machines B and C the service stays divided in probabilities, only manifesting as an effective product in daily world after protocol translation. With continuous reductions, that is, with unbroken chain of very fast reductions, availability and quickness are theoretically warranted in a level never seen before. Lastly, as pointed out by Schmidt and colleagues, the virtualized infrastructure of the bus allows it to grow or shrink according to the workload which it is supporting (Schmidt, 2005).

The one-to-many teleportation has become well known since the end of the nineties (Murao *et al.*, 2000), now considered by Ghiu (2012). Let us first establish the initial state in server A related to a half-spin particle,

$$|\psi\rangle_A = \alpha|0\rangle + \beta|1\rangle.$$

We want to broadcast the information of this state to servers B and C , so that they share the final state

$$|\Psi\rangle_{BC} = \alpha|\phi_0\rangle + \beta|\phi_1\rangle.$$

The general representation of a quantum channel shared by the three servers is given from

$$|C\rangle_{ABC} = N(|0\rangle_A |\phi_0\rangle_{BC} + n|1\rangle_A |\phi_1\rangle_{BC}),$$

where

$$N = 1 / \sqrt{1 + n^2}.$$

If we take parameter $n = 1$ we get one-to-many teleportation. Now considering Bell-states, it follows the whole system state

$$|\psi\rangle|C\rangle = \frac{N}{\sqrt{2}} \left[|\Psi_a^+\rangle(\alpha|\phi_0\rangle + \beta|\phi_1\rangle) + |\Psi_a^-\rangle(\alpha|\phi_0\rangle - \beta|\phi_1\rangle) + |\Psi_b^+\rangle(\beta|\phi_0\rangle + \alpha|\phi_1\rangle) + |\Psi_b^-\rangle(-\beta|\phi_0\rangle + \alpha|\phi_1\rangle) \right].$$

Lastly, servers B and C have to make local appropriate transformations to get final state

$$|\psi\rangle = \frac{1}{\sqrt{|\alpha|^2 + n^2|\beta|^2}} (\alpha|\phi_0\rangle + n\beta|\phi_1\rangle) = \alpha|\phi_0\rangle + \beta|\phi_1\rangle.$$

Now we apply the metalanguage defined above. Each elementary service has a complete state function, so that, with Bell-basis, we may write for the whole system

$$S^4\langle f | \wedge \frac{N}{\sqrt{2}} \left\| \begin{array}{l} \langle \psi_1 \succ \langle \psi_2 \succ \psi_3 \rangle \succ \langle \psi_4 \succ \psi_5 \succ \psi_6 \rangle \rangle \\ \langle \psi_1 \succ \langle \psi_2 \succ \psi_3 \rangle \succ \langle \psi_4 \succ \psi_5 \rangle \succ \psi_6 \rangle \rangle \\ \langle \psi_1 \succ \langle \psi_2 \succ \psi_3 \rangle \succ \langle \psi_4 \succ \psi_5 \succ \psi_6 \rangle \rangle \\ \langle \psi_1 \succ \langle \psi_2 \succ \psi_3 \rangle \succ \langle \psi_4 \succ \langle \psi_5 \succ \psi_6 \rangle \rangle \rangle \end{array} \right\|, \quad (17)$$

So we can say that the functional applied to the right in the above expression corresponds to the initialization of the quantum channel between the functions ψ_i that make up the orchestration S^4 , so that, for each elementary service s_i we have

$$\psi_i = \left[|\Psi_{i,A}^+\rangle(\alpha|\phi_0\rangle + \beta|\phi_1\rangle) + |\Psi_{i,A}^-\rangle(\alpha|\phi_0\rangle - \beta|\phi_1\rangle) + |\Psi_{i,B}^+\rangle(\beta|\phi_0\rangle + \alpha|\phi_1\rangle) + |\Psi_{i,B}^-\rangle(-\beta|\phi_0\rangle + \alpha|\phi_1\rangle) \right].$$

DISCUSSION

According to *Definition 1* and *Axiom 1*, S^1 has flexible nature enough to incorporate virtually any weak coupling O^1 on s_i services. Based on the *Definition 2* and the *Axiom 2*, this flexibility extends to n dimensions according to *Definition 4*, which states that in practice an array of identified weak couplings is executable under demand and according to the availability of resources. *Definition 3* requires logistical criteria previously established in the architecture itself. It is worth remembering that both auxiliary services and application services fall within the formal framework described above.

The word “agglomerate” was used rather than “cluster” precisely to avoid confusion with the concept of “cluster of machines”. Based on quantum principles, Server A arrived at the best possible solutions in four dimensions. During the short period of processing, the computer repeated the test in hundreds of different ways to make sure that there was not a better selection of ways to perform the required task. Thus, given a cloud under a SOA overlay disposing services $s_1, s_2, s_3, s_4, s_5, s_6$, this agglomerate shall be analyzed in server B according to local environmental conditions. The advantage is that the teleported matrix already contains the best selections of orchestrations on the same services for a certain global task to be replied in a remote location.

Due to the uncommon nature of the qubit itself, in comparison with the classical bit, quantum computers are expected to prove in labs to be able to operate many times faster executing complex tasks of analysis and recombination. Nevertheless, as Nielsen and Chuang pointed out, “we do not understand what exactly it is that makes quantum

computers powerful, or on what class of problems they can be expected to outperform classical computers” (Nielsen & Chuang, 2000). In fact, our example of orchestration was a simple one, but in reality quantum servers shall deal with a high number of services and dimensions, a situation now difficult to govern by common computers. In addition, quantum principles applied in computation should help to solve the most challenging problem in computer science: the construction of learning machines. By making computers select and analyze teleported agglomerates (as server *B*) based on previous experiences (server *A*), there is hopeless to improve artificial intelligence in clouds for complex decisions related to global scenarios of production. I think that there shall be not by way of individual processing but by metacomputation that we shall obtain the best performance gains and cyber intelligence with quantum machines.

SPONTANEOUS ENTANGLEMENT

In fact, the creation of a pair of qubits from one qubit, as presented previously, is understandable as an outcome of the growth in the complexity of cybernetic autonomous devices of information interchanging and their links, but changes of complexity stay obscure; they require spontaneous entanglement. This is what keeps physicists separate from the world outside the laboratory.

Quantum processors need to operate at superconductivity regime in order to make superposition happen. A viable way to achieve this is using metal niobium and lowering the temperature of the apparatus to -272.98°C, close to absolute zero. This is a physical precondition to hold quantum phenomena. It happens that spontaneous entanglement is a response to complex stimuli from the environment; the more you induce the increasing required complexity of the system, the more you rise the chances of new entanglements. As the phenomenon of mutation useful for the survival of a species, or the emergence of new synapses in the brain, allowing connections between in-

tellective processes, it is not known precisely how occurs spontaneous quantum entanglement between qubits from the incitement of the process until the conflagration of the fact itself; it is an evolutionary interval that remains confined to a black box. Spontaneous entanglements are not observed, in the same way that it is not feasible a snapshot of the natural extinction of a species.

A METAFRAME FOR CLOUDS IN HILBERT SPACE

Constructions of type-cloud are more than sets of devices. Clearly, there is a succession of scales if we agree that to be a member of the larger system (cloud), the element (server) must be enrolled in some metric with tier below the tier of the metric of the first. Altaisky (2001) understood very well the problem of formal description of complex cybernetic systems, including systems of type-cloud. A state function to describe the members x (servers) of an object X (cloud) would be

$$\{\Psi(X), \Psi(X, x)\},$$

being $\Psi(X)$ the global state function and $\Psi(X, x)$ the state function of the elements. Since the $\Psi(X, x)$ are in $\Psi(X)$, it is not valid the commutation rule

$$[\Psi(X), \Psi(X, x)].$$

This means that, in principle, we can not apply operators on these functions such that we can measure both simultaneously; either we observe the overall behavior of the cloud, or the isolated behavior of one of its members. In theoretical terms, in a perfectly entangled quantum cloud, to measure the state of a server blurs the overall state of the cloud and vice versa. As the objects $\Psi(X, x)$ and $\Psi(X)$ inhabit different functional spaces,

their signatures or sets of coordinates associated with them assume a hierarchical network. Each level of the hierarchy is described by the structure

$$\mathcal{M} = \langle \ell, \beta^\ell, T^{\beta^\ell} \rangle$$

in which

$\ell \rightarrow$ the signature of scale,

$\beta^\ell \rightarrow$ the symmetry group at scale ℓ ,

$T^{\beta^\ell} \rightarrow$ some topology on β^ℓ (in other words, the coordinates at ℓ -th level).

In Hilbert space $\mathcal{H}$ of these hierarchical states,

$$\Psi_1, \Psi_2 \in \mathcal{H}; \alpha, \beta \in C \Rightarrow \alpha\Psi_1 + \beta\Psi_2 \in \mathcal{H},$$

where C is the set of the complex numbers, we would have for the general state, by definition,

$$\alpha\Psi(X) = \left\{ \alpha\psi_X^{\ell_1}(\tau^{\beta^{\ell_1}}), \right. \\ \left. \left\{ \alpha\psi_{X_{x_1}}^{\ell_2}(\tau_1^{\beta^{\ell_2}}), \dots, \alpha\psi_{X_{x_n}}^{\ell_2}(\tau_n^{\beta^{\ell_2}}) \right\}, \dots \right\},$$

remembering that by the re-ingoing nature of $\Psi(X)$ there is no commutation.

The structure of $\mathcal{M}$ is enough to preach cybernetic systems of type “cloud”, although here I have provided only a brief formalism. This structure includes complexities such as dynamic provisioning of computing resources, dynamic balancing of the workload and performance monitoring. The application of cloud computing is a reality on the Internet (Google and Yahoo). In 2008 the total of the clouds of the five largest Internet search companies amounted to around 2 million servers. The main advantage of this computational model is the significant reduction of

the time-to-market for on-demand e-business and Web 2.0 applications, that is, the gradual allocation of resources by necessity.

THE BEEHIVE EFFECT

Quantum communication uses the informational content of entangled systems in order to obtain an extra resource. Quantum entanglement is essential to reach the exponential speed-up anticipated by some quantum algorithms. From the theoretical point of view, all the information in a state of maximum entanglement is contained in the joint properties of the systems and not in individuals separately. The so-called “beehive effect” originates from a large scattering of entangled states distributed across multiple quantum servers via broadcast channels. Aiming to make an effective distribution of information by entangled states we would have to build a linked set of transmitters like in the most stable going experiments in which we start from the distribution of entangled photons through glass fibers, since they are installed underground and thus they are less vulnerable to external disturbances. Eventually, it will be necessary the use of satellite technology. Due to the spread of entangled states over arbitrary distances, the cloud assumes a global behavior from each stimulus locally introduced. The global response is resulting not only from the entanglement, but also from the state analysis promoted by auxiliary services of SOA architecture on the entangled states.

It is usual to expect that quantum computing comes to fruition in the next ten/twelve years, mainly solving problems about the transfer of large amounts of complex data by teleporting based on quantum entanglement. The evolution to an intelligent cloud of entangled quantum servers with the ability to send and receive large amounts of data analyzing and deciding what to do is a more distant win I suppose, but even so it would be risky to make estimates from the present stage of research.

FUTURE RESEARCH DIRECTIONS

In the future, clouds will be able to make global decisions supported by entangled states of information shared among all quantum servers, including via teleportation of entanglement itself. As well as, local decisions will be madden after the beehive analysis of the situation, a complex task which requires multiple entanglements and teleportations. Quantum cloud computing is still in its infancies, but it is very far from science fiction.

CONCLUSION

Physicists agree on that we are a long way off —decades, they suppose — from employing quantum features to build quantum hardware with practical applicability (Woo, 2013). The correlation quantumness between particles is in principle given by entanglement, and entanglement is very sensible to environmental perturbations, which turns impracticable to maintain superposition of states. Researchers are now working on new ideas to quantify the disagreement (the “discord”) between quantum and classical ways of calculating the same property as a manner to solve the problem of sensibility to the environment, but it is still not clear if discord really fulfills general computing quantumness (Tyler, 2013). As Professors Hadjiivanov and Todorov said,

Quantum mechanics, created during the first quarter of XX century is finding wide applications only after the invention of the transistor in 1948 and the development of the laser in the late 1950's. The true applications of the 'second quantum revolution' are yet to come. (Hadjiivanov & Todorov, 2015).

Currently, with the improvement of laser technology, there are several advanced experiments

applying quantum entanglement/teleportation over distances of about 89 mi. We expect that computers endowed of quantum microprocessors shall develop capabilities to perform what I call “self-entanglement”, transmitting packets of entangled states with embedded spinor-like gates to other computers in a cloud, interacting with high efficiency by teleportation of states. The “quantum cloud” will be many times faster to provide services than any conceived architecture now available. This is the beginning of an increasing intelligence, since entanglement and teleportation open doors to infinity of interactions from server to server.

ACKNOWLEDGMENT

I acknowledge Doctor José Abdalla Helayël-Neto, at Brazilian Center of Physics Research, by the great support to this work.

KEY TERMS AND DEFINITIONS

Beehive Effect: The supposed global — and even intelligent — behavior of a cloud of servers acting under quantum principles.

Cloud Computing: A model of computation by which IT resources are randomly dispersed in the network, being offered as services.

Progenitor: The gate generator of a two-qubit system which under the action of a control gate creates a pair of entangled states.

Quantum Bit (or Qubit): The quantum tile of information that can assume both states 0 and 1 at the same time.

Quantum Entanglement: The matting of quantum states to which decomposition does not hold.

Quantum Machine: A computer whose general operation follows the laws of quantum mechanics.

Quantum Teleportation: The long-distance replication of a quantum state.

SOA (Service Oriented Architecture): A computational architecture for the provision of services as packages of specific tasks over the network.

ENDNOTES

¹ A symmetry in quantum mechanics is a discrete transformation or a group of continuous transformations that let invariant the Hamiltonian (or the Lagrangian) and the canonical commutation relations of the system.

² The atom is not immediately perceptible to our senses, and any experiment takes only a specific property of the atom to the ambit of a mediated sensibility.

³ Every experiment is a material act which is simultaneously an act of perception.

INTRODUCTION

Computers accelerate our ability to achieve scientific breakthroughs. As technology evolves and new research needs come to light, the role for cyberinfrastructure as “knowledge” infrastructure continues to expand. In essence, cyberinfrastructure can be thought of as the integration of supercomputers, data resources, visualization, and people that extends the impact and utility of information technology. This article defines and discusses cyberinfrastructure and the related topics of science gateways and campus bridging, identifies future challenges in cyberinfrastructure, and discusses challenges and opportunities related to the evolution of cyberinfrastructure and cloud computing.

BACKGROUND

Today’s US national cyberinfrastructure ecosystem grew out from the National Science Foundation-funded supercomputer centers program of the 1980s (National Science Foundation, 2006). Four centers provided supercomputers and support for their use by the US research community. Researchers generally accessed one supercomputer at a time, sometimes logging into a front-end interface. At this time, the focus of the research computing community was centered on supercomputers – traditionally defined as computers that are among the fastest in existence. Over time there have been several different supercomputer architectures, but the key points were that supercomputers were monolithic systems that were among the fastest in the world. At present we can think of supercomputers as being a subset of the more general term high performance computer (HPC) – where HPC means that many computer processors work together, in concert, to solve large computational

DOI: 10.4018/978-1-5225-2255-3.ch092

challenges and where the computer processors communicate via very fast, networks internal to the HPC system. HPC focuses on computing problems where a high degree of communication is needed among the processors working together on a particular problem. HPC is a more general term than supercomputers because there are many HPC systems that are modest in total processing capacity relative to the fastest supercomputers in the world (cf. Top500.Org, 2016).

In the early days of supercomputing, using multiple supercomputers in concert was not possible. In the late 1980s, the National Research and Education Network initiative created several testbeds for distributed computing, including the CASA testbed which linked geographically distributed supercomputers to solve large-scale scientific challenges (U.S. Congress Office of Technology Assessment, 1993). A turning point in distributed high performance computing was the I-WAY project – a short-term demonstration of innovative science enabled by linking multiple supercomputers with high performance networks (Korab & Brown, 1995). It demonstrated the possibilities to advance science and engineering by linking supercomputers using high-speed networks.

In the late 1990s, the NASA Information Power Grid provided a production grid of multiple supercomputers connected by a high-speed network (Johnston, Gannon, & Nitzberg, 1999). Around this time began also the concept of high throughput computing (HTC) with a software system called Condor (Litzkow, Livny, & Mutka, 1988). HTC takes the approach of breaking a problem up into small pieces of work and distributing them to multiple CPUs over network connections that may be relatively slow. HTC best suits problems where relatively little communication is needed among the processors working together on a particular problem or simulation. Because HTC applications can operate relatively efficiently on processors with little communication among the processors, HTC applications have always fit naturally into a distributed computing environment (Thain,

Tannenbaum, & Livny, 2005). Today, a popular framework for distributed storage and processing of large data sets is Apache Hadoop (The Apache Software Foundation, 2006).

Over time, distributed computing evolved into ‘grids,’ with grids emerging as a commonly used term in the late 1990s. Typically, computational grids are the hardware and software infrastructure which provides access to the computational capabilities (Foster & Kesselman, 1998, 2004). *Middleware* is a key software component of cyberinfrastructure, enabling the disparate components of cyberinfrastructure to work together. In effect, middleware manages complex interactions between resources which allows for the development of new networked applications (National Science Foundation, 2004). Around the turn of the century, the US government funded two major grid projects – TeraGrid and the Open Science Grid. In 2001, the NSF funded an experimental computational, storage, and visualization resource called TeraGrid, which developed grid capabilities for supercomputer centers (National Science Foundation, 2006). The Open Science Grid (OSG) (Livny et al., 2006; Open Science Grid, 2015), first funded with that name in 2006, grew out of three projects that developed HTC grids for the purpose of analyzing data from physics experiments (Avery, 2007).

Tying geographically distributed computing systems together into grids to create a whole greater than the sum of its parts was widespread around the turn of the century. However, the term grid computing was becoming laden with sometimes competing definitions. In addition to computing and data grids, other terms such as collaboration, semantic, and peer-to-peer grids emerged, distinguished by the characteristics of the protocols and interactions between components (Fox, 2006). The potential for confusion and competing definitions of different types of grids led Dr. Ruzena Bajcsy, then NSF assistant director of the Computer and Information Science and Engineering Directorate, to use the term cyberinfrastructure when charging a new advisory group to offer advice to

the NSF – the “Blue Ribbon Advisory Panel on Cyberinfrastructure.” The term cyberinfrastructure had been used before, in a different sense, by Richard Clarke, then US National Coordinator for Security, Infrastructure Protection, and Counterterrorism (Clarke & Hunker, 1998). Bajcsy stated that she used the term cyberinfrastructure because she wished to “create a program ... that would involve the broader computer science/information technology community” (Bajcsy, 2013). The committee report goes on to state, “the newer term cyberinfrastructure refers to infrastructure based upon distributed computer, information and communication technology. If infrastructure is required for an industrial economy, then we could say that cyberinfrastructure is required for a knowledge economy” (Atkins et al., 2003).

Bajcsy’s successor at the NSF, Dr. Peter Freeman, stated that this report “led to the creation of a term for infrastructure that attempts to capture the integration of computing, communications, and information for the support of other activities (especially scientific in the case of NSF)” (Freeman, 2013). In 2007, Freeman wrote “cyberinfrastructure can have many definitions and, to some extent, the definition is in the eye of the beholder” (Freeman, 2007). To make it clearer for scientists outside of science and physics, Indiana University developed a definition identifying components and function:

Cyberinfrastructure consists of computing systems, data storage systems, advanced instruments and data repositories, visualization environments, and people, all linked together by software and high performance networks to improve research productivity and enable breakthroughs not otherwise possible. (Stewart et al., 2010)

The EDUCAUSE Campus Cyberinfrastructure Working Group and the Coalition for Academic Scientific Computation developed a definition which includes teaching and learning:

Cyberinfrastructure consists of computational systems, data and information management, advanced instruments, visualization environments, and people, all linked together by software and advanced networks to improve scholarly productivity and enable knowledge breakthroughs and discoveries not otherwise possible. (Dreher et al., 2009)

The characteristics distinguishing cyberinfrastructure from other IT terms and concepts is the inclusion of resources like instruments and sensor networks as well as people and a focus on knowledge breakthroughs. Cyberinfrastructure may be distinguished in particular from the more European term eScience on the basis of the explicit role of people in cyberinfrastructure. eScience is defined as “the large scale science that will increasingly be carried out through distributed global collaborations enabled by the Internet. Typically, a feature of such collaborative scientific enterprises is that they will require access to very large data collections, very large scale computing resources and high performance visualization back to the individual user scientists” (National e-Science Centre, 2010).

CYBERINFRASTRUCTURE TODAY

The broad use of cyberinfrastructure in science and engineering envisaged by Bajcsy is in ample evidence today. That cyberinfrastructure enables breakthroughs not otherwise possible is demonstrated by two Nobel prizes for work made possible by major cyberinfrastructure resources – the Open Science Grid and XSEDE.

The Open Science Grid is an international HTC resource. Many different organizations own the computers participating in the grid (Open Science Grid, 2015). OSG’s people part of cyberinfrastructure is organized through dozens of Virtual Organizations (VOs) that use the computational resources of the OSG, each supporting its own uses and users. Analysis of data from the Large

Hadron Collider (LHC) is the paradigmatic use case for HTC. LHC data can be broken down into large numbers of small data sets, each of which may be analyzed in isolation. The 2013 Nobel Prize for Physics was awarded to François Englert and Peter Higgs for the theoretical discovery of the particle now known as the Higgs Boson. The existence of the Higgs Boson was verified in experiments at the LHC, with the data analyses made possible by the OSG.

The largest HPC-oriented cyberinfrastructure in the use is the eXtreme Science and Engineering Discovery Environment (XSEDE) (Towns et al., 2014). XSEDE is a single, virtual system which is comprised of a collection of integrated and highly-advanced digital resources and constitutes the largest HPC resource funded by the US government (Towns et al., 2014; XSEDE, 2013, 2015). The 2013 Nobel Prize in Chemistry was awarded to Martin Karplus, Michael Levitt and Arieh Warshel, for the development of multiscale computer models of complex chemical systems. Karplus used resources of the TeraGrid, the predecessor of XSEDE, and Warshel uses resources of XSEDE (XSEDE, 2015).

Cyberinfrastructure may support a particular research domain or application. Cyberinfrastructure has also been widely adopted in the private sector, particularly in advanced engineering, medicine and pharmaceuticals, mining and oil exploration, finance, and manufacturing (Tabor Griffin Communications, 1998).

Cyberinfrastructure systems need not be massive to be important. A Specialized cyberinfrastructure supports NASA's *Operation IceBridge* in measuring polar ice sheets in Greenland and Antarctica. *Operation IceBridge* uses sophisticated synthetic aperture radar (SAR) systems to study polar ice and map the bedrock base in Greenland and Antarctica (Hayden, Fox, & Gogineni, 2007; Knepper, Link, & Standish, 2015). One of the characteristics of SAR is that one doesn't get an image out of SAR systems directly; a great deal of computation is required to generate an image. In-plane computation and data storage provide real-time analysis of multiple radar data sources (Figure 2). This cyberinfrastructure is highly specialized to deal with the rigors of fieldwork in Antarctica. The cyberinfrastructure designed to support *Operation IceBridge* enables real-time

Figure 1. The open science grid

Figure 2. NASA operation icebridge field radar data processing cyberinfrastructure

Source: Knepper, Standish, & Link 2015

reactions to data as it is being collected in an airplane over the Antarctic ice sheets – something not possible before this system was developed.

EVOLVING COMPONENTS OF CYBERINFRASTRUCTURE INCLUDING CLOUD COMPUTING

In his 2007 article, Freeman stated that the definition of cyberinfrastructure will evolve over time (Freeman, 2007). Cloud computing can thus be thought of as a particular approach to computing infrastructure and as a component of cyberinfrastructure which includes computational resources and data storage resources. According to the National Institute of Standards and Technology (NIST),

Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and

released with minimal management effort or service provider interaction. (Mell & Grance, 2011)

Key in cloud computing are on-demand self-service, broad network access, resource pooling, rapid elasticity, and measured service. It can be used as a solution to applications that are “hosted in the cloud” or integrated into cyberinfrastructure. Like a high performance computer, a cloud computing solution can be monolithic or integrated into a larger cyberinfrastructure facility. For example, the NSF recently funded a cloud system that will be integrated as part of XSEDE called Jetstream (Stewart et al., 2015). It can be used in isolation as a scientific cloud system or as part of a larger integrated cyberinfrastructure facility.

Data storage systems, advanced instruments and data repositories have also changed over time. Some recent changes in needs and data resources are described in the final report of the NSF Advisory Committee for Cyberinfrastructure Task Force on Data and Visualization (NSF Advisory Committee for Cyberinfrastructure Task Force on Data and Visualization, 2011) and the work

from Hey, Tansley, and Tolle (2009). The NSF has recently funded a new data-oriented storage and analytics facility called Wrangler to add new resources for big data to the US infrastructure funded by the NSF and supported by XSEDE.

Middleware has evolved significantly since the early days of cyberinfrastructure. Globus, one of the most widely used families of software in the world, now includes authentication, secure access capabilities, and data and metadata management tools (Foster, 2005; Globus Online, 2013). Other middleware includes workflow systems that coordinate the use of cyberinfrastructure and automate complex analyses; examples include Apache Airavata (Maru et al., 2011), Kepler (Ludäscher et al., 2006), and Pegasus (Deelman et al., 2005).

Visualization systems — hardware (display, visualization, and interaction) and software (applications, libraries, middleware, and data format standards) — have evolved dramatically since the inception of the term cyberinfrastructure. Visualization was one of the earliest cyberinfrastructure components to promote distributed applications and high levels of interoperability, largely because of the network of homogeneous CAVE Automatic Virtual Environments (CAVEs) and smaller devices using similar software launched in the last half of the 1990s (NCSA, 2001). Us-

ers at multiple sites could synchronously interact with the same data sets and observe remote participants via virtual avatars while communicating over IP-based audio and video channels. CAVEs and similar devices introduced new capabilities for understanding complex 3D and 4D data from other cyberinfrastructure resources. However, cost and scarcity, limited their impact on day-to-day scientific investigation. The 2000s saw affordable graphics cards, projectors, and high-definition, stereoscopic displays. Consumer-level technologies spurred a range of innovative systems for stereoscopic and ultra-resolution visualization (Sherman, O’Leary, Whiting, Grover, & Wernert, 2010), democratizing advanced visualization systems and techniques. Figure 3 shows a CAVE diagram and an ultra-high resolution tiled wall assembled from commodity HD televisions. Shown in the figure at right, scholars at Indiana University’s Mathers Museum of World Cultures use an IQ-Wall to compare high-resolution images of textiles. This 3x4 wall is free-standing and was installed in a museum gallery in an afternoon. Such a display wall, which supports collaborative research, can now be created for a few tens of thousands of dollars, making them widely accessible in research environments.

Figure 3. At left is a CAVE, a room-scale visualization environment. At right is an ultra-high resolution tiled wall built in 2013 using commodity HDTV displays.

FUTURE RESEARCH DIRECTIONS

Cloud Computing, Cyberinfrastructure, Exascale Computing, and the Economics of Computing

Cloud computing and more traditional HPCs (supercomputers) have complementary strengths and weaknesses. Cloud computing facilities may have internal networks of modest speed compared to supercomputers. On the other hand, cloud computing may be purchased in modest increments and are thus more accessible to a larger user community than supercomputers. Cloud computing is commonly used for “big data” applications, characterized by data volume, velocity, and variety (Laney, 2001). US President Obama’s recent executive order (Obama, 2015) sets a new agenda for the creation of exascale computing facilities (capable of 10^{15} mathematical operations per second) while calling for joint development of exascale and big data/cloud computing facilities. Fox and collaborators (Fox, Qui, Kamburugamuve, Jha, & Luckow, 2015) depict many of the commonalities between cloud computing and HPC and propose an alignment and set of commonalities between HPC and big data stacks that can form a foundation for the sort of joint development of both approaches called for by President Obama in his recent executive order.

Cloud computing and HPC need not be an “either/or” choice. There are business cases for selecting cloud computing or local servers (Brumec & VrčEk, 2013; Marston, Li, Bandyopadhyay, Zhang, & Ghalsasi, 2011). However, choosing between cloud and HPC can be very complicated as cloud resources may not be able to support science applications that require low-latency internal networks or large amounts of memory as prerequisites, even if the cost of cloud computing seems lower than HPC per CPU hour. A locally owned HPC or HTC system can be acquired as a one-time cost where the capacity of the system limits the usage over time but remains useable for

several years. In contrast, use of cloud computing may have a smaller cost for initial use but requires ongoing payments. This suggests tradeoffs in “locally owned” versus “cloud” that will suggest solutions strongly influenced by local conditions and financial systems at any given organization.

Cyberinfrastructure challenges include documenting return on investment and energy costs to operate at large scale. An analysis of return on investment in XSEDE is explored by Stewart and collaborators (Stewart et al., 2015). Energy costs and the economics of large-scale data centers help drive many activities into cloud computing. Security and data privacy are also concerns.

Science Gateways, Campus Bridging, and Cyberinfrastructure Ease of Use

For years, researchers accessed cyberinfrastructure exclusively through command-line interfaces. This sort of interface made it difficult to do long complex tasks and they were not particularly user friendly. Today, access to and the utility of cyberinfrastructure has been considerably expanded through the deployment of science gateways, use of cloud computing tools, and campus bridging. In particular, science gateways provide access to cyberinfrastructure to a broad set of users by employing graphical user interfaces and sophisticated tools for orchestrating computational workflows.

Science gateways make it possible to weave together a set of complicated tasks to achieve an overarching goal – like search for drug candidates or predict the path of a tornado. More formally, science gateways are defined as “a community-specific set of tools, applications, and data collections that are integrated together via a portal or a suite of applications” that can “support a variety of capabilities including workflows, visualization as well as resource discovery and job execution services” (Wilkins-Diehr, 2007). There are now dozens of science gateways in use or in development (Lawrence et al., 2015). For example, the CiPRES portal (Cyberinfrastructure for Phylogen-

tic Research) enabled thousands of researchers – including research students – to do sophisticated analyses of evolutionary histories from genetic information (CIPRES, 2016). Another important science gateway is SEAGrid – the Science and Engineering Applications gateway (SEAGrid, 2015). SEAGrid is geared toward chemical and mechanical analyses, and can, for example, be used to search for potential new drug candidates. The major components of SEAGrid (see Figure 4) exemplify a multi-tiered approach commonly used in science gateways.

Science gateways have also had a profound impact on citizen science—the public contribution to scientific discoveries (OpenScientist, 2011). Zooniverse is a web-based front end to several science gateways supporting citizen science. Dozens of projects use citizen science in weather, archaeology, biology, and medicine, where thousands of people help analyze research data – particularly image data – that might otherwise go unanalyzed for months or years into the future (Zooniverse, 2015).

Campus bridging approaches a different set of cyberinfrastructure issues. One of the significant challenges in cyberinfrastructure is integrating across scales of resources. Campus bridging focuses on integrating local, often modest scale cyberinfrastructure facilities with regional, na-

tional, and even international cyberinfrastructure resources. The goal of campus bridging is to “bridge” from the campus to the approach enables small or resource-constrained groups to operate as if the higher-level resources were close at hand (Hallock, Knepper, & Stewart, 2015; NSF Advisory Committee for Cyberinfrastructure Task Force on Campus Bridging, 2011). Some campus bridging issues are solvable simply with funding; for instance, networking becomes ever cheaper and it becomes ever more feasible to have good network connectivity from campus to national resources. Recent efforts have focused on technical interoperability among campus computing clusters and national level resources like XSEDE. The technical aspects of such interoperability include adding software to local institutional cyberinfrastructure systems that match those used on nationally-shared resources and as a result enabling training and educational materials developed for nationally shared systems to be used in support of smaller, local resources. Networking in support of bridging from campus to national resources has also been furthered by a network concept called the Science DMZ, which explicitly creates a portion of network “specifically engineered for science applications and does not include support for general-purpose use. By separating the high-performance science network

Figure 4. Science gateways such as SEAGrid uses a multi-tiered gateway architecture

(the Science DMZ) from the general-purpose network, each can be optimized without interfering with the other” (ESnet, 2016).

CONCLUSION

Cyberinfrastructure has evolved from supercomputer centers into an integrated and distributed suite of powerful and flexible resources that integrate supercomputers, data resources, visualization, and people in ways that go beyond the capabilities of any of the individual components of cyberinfrastructure. It has led to new products, medical treatments, and improved business processes that improve quality of life. In the long run we believe that cloud computing, high performance computing, and high throughput computing will be seen not as alternatives but as complementary tools used flexibly in response to the particular science and engineering needs and particular local conditions of researchers and organizations making use of cyberinfrastructure.

In summary, the future offers tremendous opportunities for science and society to use cyberinfrastructure to enable new discoveries and improve the quality of life of people everywhere as new tools for visualization, science gateways, campus bridging, citizen science, and cloud computing evolve and deliver new capabilities to the public and the scientific and technical communities worldwide.

KEY TERMS AND DEFINITIONS

Campus Bridging: The seamlessly integrated use of cyberinfrastructure operated with other local or remote cyberinfrastructure as if they were proximate to the user.

Citizen Science: The work of individuals or teams of amateur, non-professional, or volunteer scientists who conduct research, gather and analyze data, perform pattern recognition, and develop technology, often in support of professional scientists.

Cloud Computing: On-demand, affordable access to a distributed, shared pool of computing and storage resources, applications, and services usually via the Internet for a large number of users.

Cyberinfrastructure: Computational systems, data and information management, advanced instruments, visualization environments, and people, all linked together by software and advanced networks to improve scholarly productivity and enable knowledge breakthroughs and discoveries not otherwise possible.

eScience: Computationally intensive science carried out through distributed global collaborations enabled by the Internet, involving access to large data collections, very large scale computing resources and high performance visualization.

High Performance Computing: Many tightly integrated computer processors that run very large scale computations and data analyses quickly where communication among the many processors is required.

High Throughput Computing: A computing paradigm that focuses on the efficient execution of a large number of loosely-coupled tasks

Science Gateways: Community-developed tools, applications, and data integrated via a portal or a suite of applications, usually in a graphical user interface, and customized to the needs of specific communities.

INTRODUCTION

Computing is a study of algorithms, automation, programming the information. Programming is a way of designing algorithms which are aimed at controlling, executing the computing devices. These devices have the basic features such as the amount of data they can store and process speed to perform in a reliable time. Traditionally in

1980's desktop personal computers (PCs) are used to support in creating, editing and manipulating documents. Further, these PCs are connected to the devices like a scanner to scan the documents, printer to take hard copies of the documents, etc. Later these devices are connected together to form a simple network. Since PCs has more of devices and it occupies more space the devices like laptop, tablet, mobile phone came into the context.

Figure 1. Sample computing paradigm shift

BACKGROUND

Computing Shift from Mainframe to Cloud

There are five distinct stages that cloud computing arrived. Initially one computer terminals like keyboard monitor to access the mainframes systems. In stage1, personal computers (PCs) were used to manipulate user requirements. In stage2, several PCs were connected to form a network called local

network and user can access the PCs from their own PCs. In stage3, several local networks were connected to a global network called the internet. From the internet, the users can remotely access the systems. In stage4, the grid computing came into the context where resources were shared distributedly. The user uses PCs to access the grid. In stage5, the user employs a computing technique called cloud computing that allows users to access the resources through the internet.

Figure 2. Mainframe to cloud shift

COMPUTING TECHNIQUES ERA

Cluster Computing

A cluster computing consists of several stand-alone computers which are a distributed loosely or tightly connected system and performs several tasks which are viewed as a single system. The features of cluster computing are reducing cost, power; it uses improved network technology, availability, and scalability.

Service-Oriented Architecture (SOA)

Service-oriented architecture is a loosely coupled distributed system that follows standard protocols to provide services over a network. The aim of service-oriented architecture is to divide the problems into separate distinguishable sections and emphasizes in a single software. The feature of the service-oriented architecture is it is independent of any product or technology.

Grid Computing

Grid computing is the technology that came into the contrast of electrical power grid, which allows the resource to be shared independently between power grids. Grid computing is a loosely coupled distributed system connected over a network. Grid computers are geographically distributed and heterogeneous in nature. The feature of grid computing is it improves scalability and performance of information system.

Utility Computing

Utility computing is a technology makes computing resource available as a service and provides a resource on demand and charges them depends on the usage. Utility computing used some form of virtualization like storage virtualization and hardware virtualization. The feature of utility computing is in reducing the cost of buying a resource in rental.

Cloud Computing

Cloud computing is an enabling technology that provides access to computer resource on-demand. Cloud computing follows model pay-as-you-go models. The important properties of cloud computing are on-demand self service, broad network access, resource pooling, elasticity, and measured service.

TYPICAL COMPUTING RESOURCE

The devices that are connected physically or virtually, internally or externally to the computer systems are called resources. Basically, computing resource can be classified into two categories namely physical resource and logical resource.

Physical Resource

Physical resources are the devices that are connected physically to the system. For example, a personal computer has several components connected together like, a monitor used to display the video outputs, a keyboard to give inputs, a secondary memory disk to store the inputs and outputs and a primary memory used for processing. Henceforth we can classify physical resource as follows, central processing unit, memory, storage, workstations, network elements, sensors.

Central Processing Unit (CPU)

Cpu is one of the most important units in the computer system where most of the processing were done. In the context to cloud computing utilization of cpu is considered. That is the amount of task processed by the cpu.

Memory

In early days, memory is managed statically. Since cloud computing is dynamic there is a need to fill dynamic memory allocation techniques for

cloud computing. Basically, memory is a block to store arrived data or task based on some policies. Memory can be allocated in three ways namely, schematic memory allocation technique: were memory allocation follows policies like FIFO, LRO. Static memory allocations technique: were memory block are divided into two parts and each part is partitioned using some static ratios. Dynamic memory allocation technique: were memory block are divided into two parts and each part is partitioned dynamically.

Storage

Cloud is models were resources are accessed remotely; the data's are stored in the remote database. These storage are maintained redundantly to ensure the client that they can access the data on demand. By this way, reliability is achieved in the storage of cloud and cloud maintains this storage as service.

Workstations

Workstations are the CPUs with high processing speed and have good internet connectivity so that the user can attain good services all the times. Usually, the workstation is automated without human interaction so that high performance is attained.

Network Elements

The components like routers, hubs, switches, bridges, etc are called network elements. To build an efficient data center to cloud switches like Top of Rack (TOR) switch, End of Rack (EOR) switch, and the virtual switch was used.

Logical Resources

Logical resources are used to control the physical resources so that we can use physical resource efficiently. Some of the logical resources are operating systems, network throughput, network loads, protocols, network delays etc.

Operating System

Operating systems help in using the available resource efficiently by managing hardware's, software's, files, devices, performance, and fault tolerance.

Network Throughput

The maximum number of bits per transferred per second is called throughput. Likewise, the maximum number of data bits transferred per second in network link is called network throughput. Higher the network throughput higher network efficiently.

Network Delay

A small difference in a second or even in millisecond made a major difference in reliability, scalability, and even in performance also. For example, a delay in virtual machine setup, virtual machine migration causes a delay in availability of virtual machines. So the minimal in delay can increase the system accuracy.

Network Protocols

The irregular communication between workloads leads to inability. So, some set of rules to be defined to overcome those inability. Protocols are kinematics of identifying the devices and connect them with each other. It also setup the rules for packing the data into a message and how to transfer these data's.

VIRTUALIZATION METHODOLOGY

Virtualization is a methodology used in cloud computing to determine an abstraction of software or hardware. Virtualization provides the resource that follows go-to technology. It helps in improving a cost effective performance by hiding the physical resource and communication between these resources and users.

Table 1. Evolution of virtualization

Technology	Period	Use
Virtual Memory	Late 1950	Developed for automatic page replacement for transistorized main frame computers.
Virtual Machine	In 1960	IBM developed a first virtual machine to run multiple operating systems on a single processor machine.
Virtual Machine with Time Sharing	Mid 1960 Mid 1970	Hardware virtualization is developed. The concept of virtual machine monitor is introduced to control this hardware virtualization. Every operating system accepted to use virtualization.
Hypervisor	In 1972	IBM developed first hypervisor VM-CP.

Evolution of Virtualization

The term virtual has introduced in late 1950, in transistorized mainframe system by creating a virtual memory for page replacement. In 1960 the first virtual machines are introduced by IBM. These virtual machines allow the user to run multiple operating systems on a single processor machine. In the mid of 1960 hardware virtualiza-

tion with time sharing is introduced. The concept of virtual machine monitor is developed during this time which is used to run a virtual machine in a protected environment. In the mid of 1970, every operating system accepted to use virtualization. In 1972 IBM has developed hypervisors called VM-CP which is used to control the virtual machines. VM-CP is the type I hypervisor which runs directly on hardware to control virtual machines.

Figure 3. Basic virtualization

Terminologies and Components of Virtualization

Host Machine

A host machine is a machine that includes the resources such as, CPU, memory, hard disk, network components that were used by virtual machines,

Virtual Machine (VM)

The virtual machine is a virtualized physical machine implemented in host machine that acts as real host machines. In the host machine, it is created as a single file or a single folder. It is controlled by a software called virtual software.

Host Operating System

Host operating system (OS) is the OS installed in the host system and manages resources such as memory, processing speed of the host machine. Finally, it assigns these resources to the virtual machines on demand.

Guest Operating System

Guest operating system (OS) is the OS installed on the virtualized setting. This guest OS may be installed in the client system, physical server etc. This guest OS is controlled by hypervisors.

Hypervisor

Hypervisor or virtual machine manager (VMM) is the software that runs on the virtual machine. Each OS in the host machine has its own memory, processing speed, allocation scheme etc. The responsibility for VMM is to control the allocation of resources and memory to the VMs. There are two groups of hypervisors namely: TYPE I hypervisor and TYPE II hypervisor. The TYPE I hypervisor so called native or bare-metal hypervisor runs directly on the hardware. It is responsible for al-

locating the resources between the host machine and VMs. It does not have a separate OS on it. TYPE II hypervisor so called hosted hypervisor has a separate OS called guest OS which is responsible for allocating the resources between the host machine and VMs.

TYPES OF VIRTUALIZATION

Basically there are two types of virtualization techniques followed. One is software-based virtualization and another one is hardware-assisted virtualization. In *software-based virtualization*: the VMM are maintained as software and the hardware interface is handed over to the guest OS. Now VMM has full control over Guest OS by writing dynamic binary translation code. It has two types of virtualization Full virtualization and para virtualization. In *hardware-assisted virtualization*: the VMM is directly installed on hardware so the dynamic binary translation is removed and the performance overhead during this dynamic binary translation is overcome.

Emulation

Emulation is software created to replicate the hardware and process of a system. Guest OS need not be modified. The instructions from the guest OS should be interpreted by the host OS. This leads guest OS to slow down. So emulation suits for the systems where speed is not significant. The disadvantages of emulation are low performance and low density.

Full Virtualization/ Native Virtualization

Full virtualization is a hardware virtualization uses a hypervisor to translate the instruction to the host OS. This leads to a significant impact on system performance. Guest OS is not modified to make feel that it is running as host OS.

Figure 4. Full virtualization

Para Virtualization

The guest OS is modified and it can be able to communicate directly with the hypervisor. This tends in the reduction of instruction translation time and operational cost. The OS available to the guest is limited that depends on the availability of the hypervisor.

Operating System Level Virtualization (OSLV)

OSLV is the method to provide multiple separate user-space instances for an operating system kernel. It allows the user-space application to run independently from other software.

Figure 5. Para virtualization

Resource Virtualization

The resources such as software resource (software, applications) and hardware resource (storage, network device etc.) are shared by the guest OS. Resource virtualization is classified into

- Storage Virtualization
- Server Virtualization
- Network Virtualization
- Desktop Virtualization
- Application Virtualization

Storage Virtualization

Storage virtualization is a technique that shares the multiple physical storage resources into a single storage and managed centrally. Storage virtualization generally implemented in file systems, tape systems, and storage area network.

Server Virtualization

Server virtualization is a technique that shares a single physical machine into multiple virtual machines (VM). Each VM have its own virtual memory, virtual interface, virtual cpu, and any one the functions such as mail, file, internet.

Network Virtualization

Network virtualization is a technique that changes the physical network into software called virtual network. The networking devices such as routers, switches, port, firewall etc. A virtual network will act same as a physical network. Network virtualization is the seamless step after storage and server virtualization. The network virtualization is grouped into two namely; External network virtualization: where multiple Local Area Networks were combined to form a Virtual Local Area Network (VLAN). Internal network virtualization: where hypervisors and containers combined to control the networks.

Desktop Virtualization

Desktop virtualization is a technique, on an existing desktop running OS it creates a separate OS. There are two man groups of desktop virtualization such as, Remote Desktop Virtualization also called as server-hosted virtualization where the operations are hosted on servers and accessed by the client over the network, Local desktop virtualization also called as client- hosted virtualization where local physical systems and hardware's are virtualized and monitored by the software called hypervisor.

Application Virtualization

Application virtualization is a technique that virtualizes particular application from the desktop

Figure 6. Operating system level virtualization

installed locally in the container. The container controls the interaction of the applications and components on how to communicate with other systems and components.

VIRTUALIZATION TOOLS

In the view of computing technology, a tool is a software use to process or to control a task or a request. Henceforth, virtualization tool is a software use to achieve virtualization for hardware

or any other resource in computer systems. The virtualization tools are broadly classified into the following modes: full virtualization, para virtualization, native virtualization, Operating system level virtualization and emulators. The availability of these tools can be commercial, open source and freely available. In full virtualization mode, many tools are available, most commonly used virtualization tool is based on VMware used to manage a virtual infrastructure. The other tools of VMware are VMware workstation and VMware Venter converter that runs on open source OS.

Table 2. Comparing features of virtualization

Type	Advantage	Disadvantage
Virtualizations	• Cost of hardware implementation and cost of energy is reduced. • Backup and recovery s faster and earlier. • More Efficient.	• Considering software license. • Experts in virtualization are less. • Maintaining the resource in virtualization environment with leasing plans is difficult.
Operating system Virtualization	• Reduce overhead. • Increase performance. • Increase compatibility.	• Have one base operating system and multiple guest operating systems. • If base OS fails the entire guest OS also fails.
Hypervisors	• Guest OS can be modified or unmodified. • In an unmodified OS if any one crashed it does not affect entire OS. • Supports wide range of hardware.	• In a modified OS if any one OS fails all others guest OS also fails. • If base OS is rebooted all other guest OS also rebooted reduces availability of VM's.

VMware server is freely available tool that runs on both windows and Linux platforms. Microsoft virtual PC is a commercially available tool that only works on Microsoft platforms. In para virtualization mode xen is an open source tool used for virtual machine migration.usermode Linux (UML), Vserver, Linux container(LXC) are the open source tools available for linux hardwares. LXC is a container based virtualization tool. In native virtualization mode, QEMU is an open source tool used for heterogeneous hardware's and used as an emulator. A virtual box is a commercial tool used to control remote desktop protocols. Openvz is an open source operating system level tool used to partition the resource efficiently and it is a container based tool. Bochs is an open source emulator tool used to debug guest OS.

FAULT TOLERANCE

For a failure or fault system fault tolerance is a system that should identify the fault and recovers the failed system back without any damage.

Fault: A fault is an underlying defect of a system that leads to an error.

Error: An error is a faulty system state, which May leads to failure.

Failure: A failure is a system error that affects its functionality of a system.

Fault Detection: Fault detection is a technique used to detect a fault or error of a system.

Fault Recovery: Fault recovery is a technique used to repair a fault or to repair a failed system after fault detection.

Table 3. Comparison of virtualization tools

Tool	Virtualization type	Host CPU	Guest CPU	Host OS	Guest OS	Live Migration	License
Xen	Para Virtualization	X86,X64	X86,X64	Linux, Unix	Windows, Linux, Unix	Yes	Open Source
KVM	Full Virtualization	X86,X64	X86,X64	Linux	Windows, Linux, Unix	Yes	Open Source
Virtual Box	Full Virtualization	X86,X64	X86,X64	Windows, Linux, Unix	Windows, Linux, Unix	Yes	Commercial
VMWare	Full Virtualization	X86,X64	X86,X64	Proprietary Unix	Windows, Linux, Unix	Yes	Open Source

Figure 7. Virtualization tools

FAULT TOLERANCE TECHNIQUES

There are numerous fault tolerance techniques followed to overcome faults. Fault tolerance can be classified based on redundancy, load-balancing, and policies.

Fault Tolerance Based on Redundancy

Redundancy is the method, where multiple copies are maintained so that availability of a resource is attained efficiently. Based on redundancy fault tolerance is classified as, hardware redundancy, software redundancy, time redundancy.

Hardware Redundant Fault Tolerant

Numerous redundant modules are created to perform the function the requirement. Later the outputs were ranked and if any fault occurred, errors were removed by this ranking.

Software Redundant Fault Tolerant

In software redundant fault tolerant two or more solutions of a problem are identified. In either way, two or more versions of software are also maintained so that failures will not occur for large inputs.

Figure 8. System failure

Time Redundant Fault Tolerant

To achieve an effective fault tolerant, time redundant fault tolerant uses a technique such as it execute the result repeatedly in different hardware and software and increase the accuracy. It also executes the result with increased time with the same hardware and software.

Fault Tolerance Based on Load Balancing

Load balancing is a technique used to balance the work load of a network in a peak traffic time. Based on load balancing it is categorized into hardware load balancing, network load balancing, and dispatcher software load balancing.

Hardware Load Balancing Fault Tolerant

Hardware based load balancing controls single host IP and sends to multiple hosts using network address translation. Backup load balancers were, used to handle the failure of single host IP.

Dispatcher Load Balancing Fault Tolerant

Dispatcher load balancing handle single point failure by transmitting dispatch function to another computer after failure. It maintains a separate server to control the entire incoming request.

Network Load Balancing Fault Tolerant

Network load balancing is distributed software used to create redundancy host and controls the entire request for an efficient load balancing.

Fault Tolerance Based on Policies

There are numerous fault tolerant techniques follows some kind of policies such as creating check points, migration of tasks, replicating the task

or workflow, resubmission of the task, retrying the failed job to recovers etc. There is two kinds of fault tolerance techniques categorized based on policies such as proactive fault tolerance and reactive fault tolerance.

Reactive Fault Tolerance Technique

When a failure occurs, reactive fault tolerance follows some kind of policies and helps to recover from failed state. The following or the policies were reactive fault tolerance follows,

Check Point/Restart

The process of saving the system states periodically when a system is in the failure-free state is called checkpoint. If a failure occurred during the execution the system is restarted from the last saved check point and it is roll backed or recovered to the fail free state.

Replication

Replication is the process used to store the most commonly used data to multiple locations and ensures the availability of data when needed. The data are accessed from nearest locations when a failure occurred.

Proactive Fault Tolerance Technique

Proactive fault tolerance techniques used to predict the fault in prior state and either replaces the components that are to fail or transfer the component that is predicted to be failed to failure free component. Some of the proactive fault tolerance policies are,

1. **Software Rejuvenation:** It is used to periodically reboot the system to ensure the system is in fail free state,
2. **Self-Healing:** It is a technique used to automatically handle the failure state and

Table 4. Tools for fault tolerant technique

Fault Tolerant Policy	Tool	Technique
Reactive	HAProxy, Hadoop, Amazon E2	Replication
Reactive	HAProxy	Job migration
Reactive	SGaurd	Checkpoint/restart
Reactive	Scientific Work Flow Systems	Task Resubmission
Reactive/Proactive	Assure	Retry, Self-Healing
Reactive	Adaptive Fault Tolerance (AFTRC)	Checkpoint/restart
Reactive	Low Latency Fault Tolerance (LLFT)	Replication
Reactive	FTWS	Replication/Resubmission
Reactive	FTM	Replication
Reactive/Proactive	CANDY	Preemptive migration
Reactive	Astrolabe	Checkpoint/restart
Reactive	VisPerf	Replication
Reactive	GEMS	Checkpoint/restart
Proactive	Cloudinit.d	Software Rejuvenation

3. **Preemptive Migration:** Used to transfer the failed component based on feedback from clients.

MTTR: Mean time to repair.

Availability: is defined as the availability of a system when it is needed without any fail and able to complete the opted task. Availability of a system is given by,

$$\text{Availability (A)} = \text{MTBF} / \text{MTBF} + \text{MTTR}.$$

Reliability at time 't' is given by the probability of time 'T' to failure after time 't'.

$$R(t) = P\{T > t\}.$$

DEPENDABILITY

Dependability used to define the reliability of the system in offering a service. Dependability generally studies the following metrics: reliability, availability, confidentiality, integrity, security.

Reliability: is defined as the probability of the system performs without any variations in the system for a specific period of time. Reliability is given by,

$$\text{Reliability function} = n(t) / N$$

= Failure free elements/number of elements at time zero.

Reliability is also given by,

$$\text{Reliability } R = \text{Availability} / \text{MTBF} + \text{MTTR}.$$

MTBF: Mean time between failures.

ESTIMATING DEPENDABILITY METRICS

In general to estimate dependability metrics two models are used. One is combinatorial model and another model is a state-phase model. *Combinatorial model:* used to study the system interaction that leads to system failure in terms of the structural relation between them. *State-phase model* considers the state and event of system dynamically. Following are the models used to represent both combinatorial and state-phase models,

Table 5. Comparison of fault tolerance models

Types	Fault Tolerant Properties				Fault Tolerant Techniques & Policies				
Fault Tolerance Model	Fault Tolerance Type	Reliability	Performance	Response Time	Self-Healing	Preemptive Migration	Checkpoint/Restart	Replication	Job Migration
LLFT	Reactive Fault Tolerance	High	High	Average	No	No	No	Yes	No
FTM	Reactive Fault Tolerance	High	Low	Average	No	No	Yes	Yes	Yes
FTMC	Reactive Fault Tolerance	High	Low	Average	No	No	Yes	Yes	No
AFRTC	Proactive Fault Tolerance	High	High	Average	No	No	Yes	Yes	Yes
FTWS	Reactive Fault Tolerance	Average	Average	Average	No	No	Yes	Yes	No
Map-Reduce	Proactive Fault Tolerance	High	High	Average	Yes	Yes	No	No	No

Figure 9. Dependability models

CONCLUSION

Formal definitions of computing, computing components, virtualization, fault, error, fault tolerance, fault tolerant model are discussed. Also tools for virtualization and fault tolerance techniques are discussed. A mathematical representation of fault tolerance is modeled.

In this chapter, fault tolerant techniques for the virtual machine were discussed. Looking at the performance metrics and features of application

the fault tolerant techniques discussed here helps in improving fault tolerance.

Future Trends

Considering the limitations and problems, following problems are identified.

1. The efficiency of fault tolerant technique in the real cloud is to be evaluated.

2. A fault tolerant technique for performance overhead in the large heterogeneous cloud is modeled.
3. A complete fault tolerant technique is developed and implemented as one the service in the cloud.
4. Based on the application type an optimum fault tolerant technique is to be developed.
5. If a number of component increases it increases the probability of failure. So an efficient fault tolerance technique is modeled.

In the context of data transmission if a large amount of data is transmitted for a long distance it increases the probability of failure. Here, an efficient fault tolerance technique is modeled.

KEY TERMS AND DEFINITIONS

Cloud Customer: A cloud customer is who consumes the services provided by the cloud provider.

Cloud Models: Cloud is basically deployed in three models as public, private and hybrid.

Cloud Provider: Cloud providers are who provides the services to the customer who needs the cloud services.

Cloud Services: Cloud provides their resources as services to their customers. So the customers pay for the services and use them.

Virtual Machine Migration: The process of migrating, the virtual machine from one location to another is called virtual machine migration.

Work Load: The number of resources consumed and shared by the users for a period of time.

Fault Tolerant Data Management for Cloud Services

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

The pervasiveness of cloud services has significantly increased the dependability requirement of cloud systems. Most cloud services are implemented according to a three-tier architecture where the presentation, application logic execution, and data management are separately handled by each tier (Zhao, Moser, and Melliar-Smith, 2005). The middle-tier servers implement the application logic and they are designed to be either stateless or to only maintain session state. Hence, this separation of concerns has greatly increased the scalability of such systems because the middle-tier servers can be easily scaled out. On the other hand, this design makes the data management tier ever more important because the availability and integrity of the services hinges on the data management tier. The data must be made highly available and protected against various hardware faults and malicious attacks.

While it is relatively straightforward to ensure high availability for Web servers and application servers by simply running multiple copies according to the three-tier architecture, it is not so for a database management system, which has abundant state. The subject of highly available database systems has been studied for more than two decades and there exist many alternative solutions (Agrawal et al., 1997; Cecchet, Candea, & Ailamaki 2008; Drake et al., 2005; Garcia, Rodrigues, & Prego, 2011; Kemme, & Alonso, 2000; Patino-Martinez et al., 2005). In this article, we provide an overview of two most popular database high availability strategies, namely database replication and database clustering. The emphasis is given to those

that have been adopted and implemented by major database management systems (Banker 2011; Davies & Fisk, 2006; Vallath 2004).

BACKGROUND

A database management system consists of a set of data and a number of processes that manage the data. These processes are often collectively referred to as database servers. The core programming model used in database management systems is called transaction processing. In this programming model, a group of read and write operations on the some data set are demarcated within a transaction. A transaction has the following ACID properties (Gray & Reuter, 1993):

- **Atomicity:** All operations on the data set agree on the same outcome. Either all the operations succeed (the transaction commits), or none of them are (the transaction aborts).
- **Consistency:** If the database is consistent at the beginning of a transaction, then the database remains consistent after the transaction commits.
- **Isolation:** A transaction does not read or overwrite a data item that has been accessed by another concurrent transaction.
- **Durability:** The update to the data set becomes permanent once the transaction is committed.

An example of an atomic transaction is shown in Figure 1. This transaction involves a debit

DOI: 10.4018/978-1-5225-2255-3.ch094

Figure 1. An example of atomic transactions

operation on a savings account and a credit operation on a checking account. If both operations are successful and the user decides to commit the transaction, the changes to both accounts are made permanent, as shown in Figure 1(a). On the other hand, if the user decides to abort the transaction, the changes to both accounts will be reversed so that the account balances of both accounts are restored to the values at the beginning of the transaction, as illustrated in Figure 1(b).

To support multiple concurrent users, a database management system uses sophisticated concurrency control algorithms to ensure the isolation of different transactions even if they access some shared data concurrently (Bernstein *et al.*, 1987). The strongest isolation can be achieved by imposing a serializable order on all conflicting read and write operations of a set of transactions so that the transactions appear to be executed sequentially. Two operations are said to be *conflicting* if both operations access the same data item and at least one of them is a write operation, and they belong to different transactions. Another popular isolation model is the snapshot isolation. Under the snapshot isolation model, a transaction performs its operations against a snapshot of the database taken at the start of the transaction. The transaction will be committed if the write operations do not conflict with any other transaction that has committed since the snapshot was taken. The snapshot

isolation model can provide better concurrent execution than the serializable isolation model.

A major challenge in database replication, the basic method to achieve high availability, is that it is not acceptable to reduce the concurrency levels. This is in sharp contrast to the replication requirement in some other field, which often assumes that the replicas are single-threaded and deterministic (Castro & Liskov, 2002).

To achieve high availability, a database system must try to maximize the time to operate correctly without a fault and minimize the time to recover from a fault. The transaction-processing model used in database management systems has some degree of fault tolerance in that a fault normally cannot corrupt the integrity of the database. If a fault occurs, all ongoing transactions will be aborted on recovery. However, the recovery time would be too long to satisfy the high availability requirement. To effectively minimize the recovery time, redundant hardware and software must be used. Many types of hardware fault can in fact be masked. For example, power failures can be masked by using redundant power supplies, and local communication system failures can be masked by using redundant network interface cards, cables and switches. Storage medium failures can be masked by using RAID (redundant array of inexpensive disks) or similar techniques.

To tolerate the failures of database servers, several server instances (instead of one) must be used so that if one fails, another instance can take over. The most common techniques are database replication and database clustering. These two techniques are not completely distinct from each other, however. Database replication is typically used to protect against total site failures. In database replication, two or more redundant database systems operate in different sites, ideally in different geographical regions, and communicate with each other using messages over a (possibly redundant) communication channel. Database clustering is used to provide high availability for a local site. There are two competing approaches in database clustering. One uses a shared-everything (also referred to as shared-disk) design, such as the Oracle Real Application Cluster (RAC) (Valath 2004). The other follows a shared-nothing strategy, such as the MySQL Cluster (Davies & Fisk, 2006) and most of DB2 shared database systems. To achieve maximum fault tolerance and hence high availability, one can combine database replication with database clustering.

DATABASE REPLICATION

Database replication means that there are two or more instances of database management systems, including server processes, data files and logs, running on different sites. Usually one of the replicas is designated as the primary and the rest of the replicas as backups. The primary accepts users' requests and propagates the changes to the database to the backups. In some systems, the backups are allowed to accept read-only queries. It is also possible to configure all replicas to handle users' requests directly. But doing so increases the complexity of concurrency control and the risk of more frequent transaction aborts.

Depending on how and when changes to the database are propagated across the replicas, there are two different database replication styles, often referred to as eager replication and lazy replica-

tion (Gray & Reuter, 1993). In eager replication, the changes (i.e., the redo log) are transferred to the backups synchronously before the commit of a transaction. In lazy replication, the changes are transferred asynchronously from the primary to the backups after the transactions have been committed. Because of the high communication cost, eager replication is rarely used to protect site failures where the primary and the backups are usually far apart. (Eager replication has been used in some shared-nothing database clusters.)

Eager Replication

To ensure strong replica consistency, the primary must propagate the changes to the backups within the boundary of a transaction. For this, a distributed commit protocol is needed to coordinate the commitment of each transaction across all replicas. The benefit for doing eager replication is that if the primary fails, a backup can take over instantly as soon as it detects the primary failure.

The most popular distributed commit protocol is the two-phase commit (2PC) protocol (Gray & Reuter, 1993). The 2PC protocol guarantees the atomicity of a transaction across all replicas in two phases. In the first phase, the primary (which serves as the coordinator for the protocol) sends a prepare request to all backups. If a backup can successfully log the changes, so that it can perform the update even in the presence of a fault, it responds with a "Yes" vote. If the primary collects "Yes" votes from all backups, it decides to commit the transaction. If it receives even a single "No" vote, or it times out a backup, the primary decides to abort the transaction. In the second phase, the primary notifies the backups of its decision. Each backup then either commits or aborts the transaction locally according to the primary's decision and sends an acknowledgment to the primary.

As can be seen, the 2PC protocol incurs significant communication overhead. There are also other problems such as the potential blocking if the primary fails after all backups have voted to

commit a transaction (Skeen, 1981). Consequently, there has been extensive research on alternative eager replication techniques, e.g., the epidemic protocols (Agrawal et al., 1997; Stanoi et al., 1998), and multicast-based approaches (Kemmer & Alonso, 2000; Patino-Martinez et al., 2005). However, they have not been adopted by any major commercial product due to their high overhead or complexities.

Lazy Replication

Most commercial database systems support lazy replication. In lazy replication, the primary commits a transaction immediately. The redo log, which reflects the changes made for the recently committed transactions, is transferred to backups asynchronously. Usually, the backup replicas lag behind the primary by a few transactions. This means that if the primary fails, the last several committed transactions might get lost.

Besides the primary/backup replication approach, some database management systems allow a multi-primary configuration where all replicas are allowed to accept update transactions. If this configuration is used with lazy replication, different replicas might make incompatible decisions, in which case, manual reconciliation is required.

DATABASE CLUSTERING

In recent several years, database clustering has evolved to be the most promising technique to achieve high availability as well as high scalability (Vallath 2004; Davies & Fisk, 2006). Database clustering, as the name suggests, uses a group of computers interconnected by a high speed network. In the cluster, multiple database server instances are deployed. If one instance fails, another instance takes over very quickly so high availability is ensured.

Database clustering not only brings high availability, but the scaling-out capability as well. Scaling-out means that the capacity of a database

management system can be dynamically increased by adding more inexpensive nodes while keeping the old equipment.

There are two alternative approaches in database clustering. In one approach, which is pioneered in Oracle RAC, adopts a shared-everything architecture. A number of other products choose to use the shared-nothing architecture. Both approaches have their challenges and advantages.

Shared Everything Cluster

In a shared-everything database cluster, all server instances share the same storage device, such as a storage area network. The cluster nodes typically connect to the shared storage device via a fiber channel switch or shared SCSI for fast disk I/O. The shared storage device must also have built-in redundancy such as mirrored disks to mask disk failures. To minimize disk I/O, all server instances share a common virtual cache space. The virtual cache space consists of local cache buffers owned by individual server instances. A number of background processes are used to maintain the consistency of the data blocks in the cache space. These processes are also responsible to synchronize the access to the cached data blocks because only one server instance is allowed to modify a data block at a time.

Each server instance has its own transaction logs stored in the shared disk. If a server instance fails, another server instance takes over by performing a roll-forward recovery using the redo log of the failed server instance. This is to ensure that the changes made by committed transactions are recorded in the database and not get lost. The recovery instance also rolls back the transactions that were active at the time of the failure and releases the locks on the resources used by those transactions.

The shared-everything design makes it unnecessary to repartition the data, and therefore, eases the tasks of cluster maintenance and management. However, this benefit does not come for free. The most prominent concern is the cost

of inter-node synchronization. Unless high-speed interconnect is used and the workload is properly distributed among the server instances, the inter-node synchronization might limit the scalability of the cluster. Also, the requirement for high-speed shared disk system also imposes higher financial cost than using conventional disks.

Shared Nothing Cluster

In a shared-nothing database cluster, each node runs one or more server instances and has its own memory space and stable storage. Essential to the shared-nothing approach, the data must be partitioned either manually or automatically by the database system across different nodes. Each partition must be replicated in two or more nodes to keep the desired redundancy level. Concurrency control and caching are carried out in each local node, and therefore, they are more efficient than those in shared-everything clusters. However, to ensure the consistency of replicated data and fast recovery, the two-phase commit protocol is often used to ensure atomic commitment of the transactions in the cluster. Comparing with the shared-everything approach, the cost of inter-node synchronization is essentially replaced by that of distributed commit.

The shared nothing approach faces the additional challenge of split-brain syndrome prevention (Birman, 2005). The split-brain syndrome may happen if the network partitions, and if each partition makes incompatible decisions on the outcome of transactions or their relative orders. To prevent this problem, typically only the main partition is allowed to survive. The minor partition must stop accepting new transaction and abort active transactions. Usually, the main partition is the one that consists of the majority of the replicas, or the one that contains a special node designated as the arbitration node (Davies & Fisk, 2006).

FUTURE TRENDS

Non-Traditional Database Systems

An interesting development in database systems is the popularity of NoSQL databases. NoSQL databases are designed to offer highly available storage services for large number of users by using weaker consistency models than those used in traditional relational database systems (Bartholomew 2010). Furthermore, such systems offer explicit user control regarding the placement of the replications. As such, NoSQL databases, such as Dynamo (DeCandia et al., 2007), MongoDB (Chodorow 2013), and Cassandra (Han et. al., 2011) are predominately used for cloud services (Bermbach et al., 2011).

In the following, we give a brief overview of the replica placement schemes and replica consistency levels offered by Cassandra. In Cassandra, three replica placement schemes are offered to users. In the default scheme (SimpleStrategy), nodes are organized into a logical ring and nodes that are next to each other on the ring are selected as replicas. In the NetworkTopologyStrategy scheme, users can choose the number of replicas from different datacenters. In the OldNetworkTopologyStrategy scheme, one replica is chosen from one datacenter, and the remaining replicas are chosen from another datacenter. Cassandra offers a variety of replica consistency levels to its users for both read and write operations. The strongest consistency level is ALL, which means the operation (read or write) would be applied to all replicas. For a read-ALL operation, it would fail if one or more replica are unavailable. A slightly weaker level is EACH_QUORUM, where the operation is applied to a quorum of replicas in every datacenter. The next weaker level is QUORUM, where the operation is applied to a quorum of replicas in any one of the datacenters. Another consistency level is

LOCAL_QUORUM, where a read/write operation would be applied to a quorum of replicas in the datacenter where the coordinator node resides. Furthermore, a user could choose to apply to one, two, or three replicas, as well as to use the SERIAL and LOCAL_SERIAL consistency levels to achieve linearizable consistency.

Beyond Crash Fault Tolerance

Existing database systems are designed to tolerate process crash fault and hardware fault. However, considering the increased pace of security breaches, future database management systems must be designed to be intrusion tolerant, i.e., they should provide high availability against a variety of security threats, such as the unauthorized deletion and alteration of database records, the disruption of distributed commit (may cause replica inconsistency), and the exposure of confidential information.

To make a database system intrusion tolerant, many fundamental protocols such as the 2PC protocol must be enhanced. There may also be a need to design special tamper-proof storage devices to protect data integrity (Strunk et al., 2000). Even though there have been intensive research in this area (Deswarte et al., 1991; Garcia, Rodrigues, & Prego, 2011; Mohan et al., 1983; Prez-Sorrosal et al., 2006; Zhang et al., 2012; Zhao, 2014), the results have rarely been incorporated into commercial products yet. The primary barrier is the high commutation and communication cost, the complexity, and the high degree of replication required to tolerate malicious fault.

CONCLUSION

Database systems are the corner stones of today's information systems. The availability of database systems largely determines the quality of service provided by the information systems. In this article, we provided a brief overview of the state of the art database replication and clustering techniques. For

many, a low-cost shared-nothing database cluster that uses conventional hardware might be a good starting point towards high availability. We envisage that future generation of database management systems will be intrusion tolerant, i.e., they are capable of continuous operation against not only hardware and process crash fault, but a variety of security threats as well.

KEY TERMS AND DEFINITIONS

Database Cluster (Shared-Everything, Shared-Nothing): A database management system runs on a group of computers interconnected by a high speed network. In the cluster, multiple database server instances are deployed. If one instance fails, another instance takes over very quickly to ensure high availability. In the shared-everything design, all nodes can access a shared stable storage device. In the shared-nothing design, each node has its own cache buffer and stable storage.

Database Recovery (Roll-Backward, Roll-Forward): Recovery is needed when a database instance that has failed is restarted or a surviving database instance takes over a failed one. In roll-backward recovery, the active transactions at the time of failure are aborted and the resources allocated for those transactions are released. In roll-forward recovery, the updates recorded in the redo log are transferred to the database so that they are not lost.

Database Replication (Eager, Lazy): Multiple instances of a database management system are deployed in different computers (often located in different sites). Their state is synchronized closely to ensure replica consistency. In eager replication, the updates are propagated and applied to all replicas within the transaction boundary. In lazy replication, the changes are propagated from one replica to others asynchronously.

High Availability (HA): The capability of a system to operate with long uptime and to recover quickly if a failure occurs. Typically, a highly available system implies that its measured uptime is

five nine (99.999%) or better, which corresponds to 5.25 minutes of planned and unplanned down-time per year.

NoSQL Database: This is a database that adopts a data storage and retrieval mechanism that is different from that used in traditional relational databases. The actual mechanisms differ in different NoSQL databases, such as key-value stores, document store, and graph, etc.

Transaction: A transaction is a group of read/write operations on the some data set that succeed or fail atomically. More accurately, a transaction

has the atomicity, consistency, isolation and durability properties.

Two-Phase Commit (2PC) Protocol: This protocol ensures atomic commitment of a transaction that spans multiple nodes in two phases. During the first phase, the coordinator (often the primary replica) queries the prepare status of a transaction. If all participants agree to commit, the coordinator decides to commit. Otherwise, the transaction is aborted. The second phase is needed to propagate the decision to all participants.

From Information Systems Outsourcing to Cloud Computing

INTRODUCTION

Outsourcing is a business term to describe a mechanism in which a company utilizes services provided by another company, normally through a contract, to fulfill some of its required business resources or functions. Outsourcing is commonly practiced by business organizations, as it is believed that it can cut costs and simplify management. For service providers, outsourcing gives them a long-term source of revenue.

Nowadays most business organizations outsource some part of their business operations. One of the most common is information systems (IS) outsourcing. This may range from computer maintenance, website development and maintenance, e-Business to the whole IS function (Dibbern, Goles, Hirschheim, & Jayatilaka, 2004). Actually, IS outsourcing is an old story which started as early as 1963 when Frito-Lay and Blue Cross & Blue Shield outsourced their data processing jobs to Electronic Data Systems (Lacity & Hirschheim, 1993). In fact, Eastman Kodak outsourced the whole of its IS functions to IBM, DEC and Businessland in 1989, 25 years ago (Gupta & Gupta, 1992). In the early stages of IS outsourcing, the issue being addressed in business organizations was whether they should outsource. Over time, the issue was no longer on whether to outsource or not to outsource, but how much to outsource (Lee, Huynh, Kwok, & Pi, 2003). This indicates that IS outsourcing has been adopted by many business organizations.

The advancement of Internet technology, especially the Web as well as high-speed and broadband access to the Internet, enabled a new computing model, “cloud” computing. The new model allows organizations to outsource some components or whole of their IS in the cloud that can be controlled and utilized from anywhere with a web browser. With this model organizations do not need to purchase hardware and expensive software licenses and surely they do not need to worry about software and hardware maintenance, which is normally a large portion of the total ownership costs of an IS to estimate the overall cost (direct and indirect) of an IS in a given time frame. Cloud computing vendors normally offer a pay-per-use method for their services, making cloud computing services like paying utilities. Perhaps cloud computing is the realization of McCarthy’s dream of utility computing, a package of computing resources that can be rented or subscribed just like other utilities (Garfinkel, 2011).

What makes the cloud computing system different from conventional computing systems? In conventional computing systems (mainframe, client-server or personal computer systems), most of the computing resources owned by an organization normally reside in the organization’s premises. The organization has to manage these resources to make sure they can be utilized to support the organization in attaining its goals. The organization incurs all costs in owning these resources, which may include investment, operation and maintenance costs. In contrast, an organization

does not need to own most of the computing resources in a cloud computing system. Instead, the organization utilizes computing resources offered by a provider and accesses the resources as needed. The organization only needs to own client devices (low cost terminals or thin clients) to utilize the computing resources through the Internet. Consequently, the organization does not need to bear the burden of all the costs mentioned previously. Of course, the organization needs to pay the provider for using the resources with a pay-per-use method of payment.

The numbers of providers offering various computing resources in the cloud are growing and some big players include IBM, Amazon.com, Google and Microsoft. These companies foresee a lucrative business in cloud computing as it offers a new business model that may attract many customers. There are three types of customers: small organizations, medium and large organizations, and consumers. However, there are some adoption issues that need to be addressed properly by providers (Kim, Kim, Lee, & Lee, 2009).

This chapter discusses concepts and applications of cloud computing. The history of the development as well as some related computing concepts such as grid computing will be highlighted. Advantages and disadvantages of cloud computing, including several issues, including adoption issues will be discussed. Future direction will be presented in the last part of this chapter. The next section will discuss the development of cloud computing, computing models and available services. Section 3 will focus more on core technology, business model and related issues, including some criticisms of cloud computing. Section 4 is the future direction and the last section (Section 5) is the conclusion.

BACKGROUND

IS outsourcing has evolved to cloud computing where many business organizations see that it is a good option to outsource their computing re-

sources to cloud computing providers. There are many definitions of cloud computing. A study on definitions of cloud computing (Vaquero, Rodero-Merino, Caceres, & Lindner, 2009) found there are at least 20 definitions. This study summarizes three necessary components of cloud computing: a large pool of computing resources accessible through a computer network, dynamically and scalable resource allocations, and a pay-per-use method of payment. The National Institute of Standards and Technology (NIST) at the U.S. Department of Commerce provides a short definition for cloud computing: “Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g. networks, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.” (Mell & Grance, 2011). Figure 1 illustrates a cloud computing models where clients’ machines access computing resources offered by cloud providers. The client machines can be desktops, laptops, smart phones, terminals or thin client machines that access the computing resources (normally computer servers) offered by cloud providers through the Internet or other networks.

There are many services that can be provided through cloud computing. In general, these services can be grouped into three service models: Software as a Service (SaaS), Platform as a Service (PaaS), and Infrastructure as a Service (IaaS). Organizations can outsource their IS through these three models. We will discuss these services with examples in the next section.

There are some pros and cons of cloud computing. However, many experts concur with McCarthy’s prediction: “Computing may someday be organized as a public utility just as the telephone system is a public utility” (Garfinkel, 2011). At the consumer level, people, especially mobile users access software and storage online as they are connected to the Internet most of the time. According to Pew Internet report on the future of cloud computing (Anderson & Rainie, 2010),

Figure 1. The cloud computing model

a solid majority of experts and stakeholders who participate in the survey on expected future of the Internet by 2020 agree that most people will access software applications and share information through the Internet using remote servers rather than local machines. Cloud computing will become dominant and will overtake desktops in the next decade.

We are witnessing smart phones overtake desktops and laptops at the consumer level. People use their smart phones to access the cloud, from sharing information through social networking sites (such as Facebook, LinkedIn, WhatsApp) to processing and sharing documents using Google Docs.

Information Systems Outsourcing and Cloud Computing

As highlighted in the introduction, IS outsourcing is not new. It started in the 60's and became a hot issue when Eastman Kodak outsourced the whole function of its IS. However, there were some successes and failures in implementing IS outsourcing and organizations need to carefully consider before outsourcing their IS to vendors (Lacity & Hirschheim, 1993).

Outsourcing is far more complex than is generally understood and IS outsourcing is even more complex. Many pros and cons have been identified and discussed in the literature (Gupta & Gupta, 1992; Palvia, 1995; Vitharana & Dharwadkar, 2007; Weidenbaum, 2005). Gonzalez (2009) studied the reasons and risks of IS outsourcing and confirmed them through surveys on large companies in Spain. With the increasing adoption of cloud computing, rapid changes in IS outsourcing is expected, as cloud computing is its latest trend (Dhar, 2012).

The development of cloud computing can be traced back to mainframe computing. In fact, virtualization—creating several virtual versions from one entity, the core technology in cloud computing, is not new as it is part of mainframe technology (Zhang, Cheng, & Boutaba, 2010). Mainframe computing relies of a powerful machine located in a specialized room. The machine is accessed via dumb terminals connected to it.

The two closely related computing models with cloud computing is grid and utility computing. Grid computing is a middleware consisting of interconnected heterogeneous computer systems in a high-speed network to solve computation-intensive problems. The idea was developed to

solve scientific problems that need intensive and high power computations in a low cost virtual supercomputer as compared to a high cost supercomputer (Buyya & Venugopal, 2005; Weinhardt et al., 2009). Utility computing is a computing model where the available computing resources can be rented based on a pay-per-use payment model.

Essentially cloud computing uses the client-server computing model where the servers belong to the providers. Users can access services offered by cloud computing servers remotely over a network (normally the Internet) through their client machines (thin client machines should be enough). To create powerful computing power it also uses the grid computing model connecting many servers using a computer network. However, unlike grid computing that connects computers from many organizations for a sharing purpose, servers in cloud computing normally belong to an organization (provider) for a commercial purpose.

Virtualization is a key enabler of cloud computing. Virtualization creates virtual versions of a real thing. Virtualization of a machine normally creates virtual versions of the machine, meaning several independent virtual machines for different purposes can be generated. In cloud computing, virtualization is used to generate virtual servers or virtual resources (such as storage) dynamically. Therefore, multiple virtual machines (possibly with different operating systems) can be generated and muted on-demand on a single machine, creating optimal flexibility (Buyya, Yeo, Venugopal, Broberg, & Brandic, 2009; Rosenthal et al., 2010; Zhang et al., 2010).

Most of the literature in cloud computing classified services offered into three clusters (Figure 2). Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) (Badger, Grance, Patt-Corner, & Voas, 2012; Sultan, 2009; Zhang et al., 2010).

IaaS providers normally possess a myriad of servers in their data centers. For example, Amazon Elastic Computer Cloud (EC2) cloud has 454,400 Linux servers (Liu, 2012) in its data centers. With

virtualization technology, EC2 can create millions of virtual servers and one or more virtual servers can serve an organization. Besides virtual servers, related services such network-accessible storages and network infrastructure components are provided on-demand (Badger et al., 2012). PaaS providers offer the infrastructure as well as application development platform. All tools for development of applications are provided by PaaS providers, including automation in designing, deploying, testing and administering applications to simplify application development (Badger et al., 2012; Zhang et al., 2010).

The most common type of cloud computing service is SaaS, accessible through the Web. Normally users access available applications on-demand using a web browser and pay the service based on the usage (per execution, per record processed, etc.). There are many SaaS vendors offering their services on the Web. Some examples are Google Apps from Google, iCloud from Apple and Adobe Creative Cloud from Adobe.

We interact with cloud applications every day such as Facebook, Twitter, YouTube, Wikis, and email (such as Live, Yahoo mail or Gmail). These applications are deployed for public or public cloud. There are four deployment models of cloud computing namely public cloud, private cloud, community cloud, and hybrid cloud (Mell & Grance, 2011; Subashini & Kavitha, 2011).

A public cloud as mentioned above is cloud infrastructure for general public use. The public has no control on the infrastructure, platform, or the applications. The cloud can be owned or managed by individuals, academic institutions, private or public organizations. A private cloud is cloud infrastructure exclusively owned and used by an organization to serve its intended users (such as workers or customers). The owner of the cloud (depending on the service model) has some control of the cloud. A community cloud is a cloud infrastructure for a particular community serving its members. It may be owned and managed by one or more entities in the community. A hybrid cloud is composed of two or three combinations

Figure 2. Cloud computing services

Source: Adapted from Yankee Group

of cloud deployment models, such as combination of private and public clouds, which serve different purposes but have same look and feel such as Google Apps.

BENEFITS, ISSUES, AND CHALLENGES OF OUTSOURCING IN THE CLOUD

The IS or IT outsourcing market is growing. According to Gartner, global IT outsourcing is predicted to reach \$ 288 billion in 2013, a slight increase (2.8 percent) from the previous year. Annual growth of the market is forecast to grow 5.4 percent. It was mentioned that cloud computing has taken away IS/IT outsourcing and caused downward pricing on IT services (Gartner, 2013; Overby, 2013). The growth of the public cloud computing market is much faster than IS/IT outsourcing in general. The global public cloud market is forecast to grow 18.5 percent in 2013 with total \$131 billion as compared to the previous year \$111 billion and IaaS segment market is predicted growing faster, 42.4 percent according to Gartner (2013).

According to 451 Research, the market size of enterprise cloud computing is expanding rapidly, much faster than the expansion of IT (451 Research, 2013). The annual growth of enterprise cloud computing is predicted to be 36

percent (Columbus, 2013b). Global spending in IaaS is predicted to reach \$16.5 billion in 2015. SaaS market will grow globally, from \$49 billion in 2015 to \$67 billion by 2018. Cloud applications have been dominating mobile data traffic globally, 81% in 2014 and reaching 90% in 2019 (Columbus, 2015).

The rapid growth of the cloud computing market is the result of growing adoption of cloud computing by the public as well as business organizations properly (Kim, Kim, Lee, & Lee, 2009). There are some obvious advantages of cloud computing, which influence its adoption. The following are some of these advantages (Armbrust et al., 2009; Buyya, Yeo, Venugopal, Broberg, & Brandic, 2009; Zissis & Lekkass, 2012).

Some Benefits of Cloud Computing

The first and important benefit of cloud computing is *simplicity and flexibility*. In a cloud computing environment, users are not required to own hardware other than terminals for connection, no software licenses needed hence users are free from the hassle of maintenance. Unlike the traditional computing model, users can scale-up and scale-down the usage as needed. Cloud computing providers normally upgrade their systems to improve services and the users should benefit from the ever up-to-date technology, both hardware and software.

The second benefit is *organizational agility*. Organizational agility is the ability of an organization to adapt quickly and effectively to the changing environment, such as rapid and effective response to customers' preferences while achieving strategic adaptation (adapting to trends and issues) in the medium term and long term shaping. As computing resources can be utilized in a very short time and portable applications or services can be developed quickly, cloud computing supports organizational agility. In addition, all services provided can be accessed any time globally with various client devices.

The third benefit is reliability and availability. Each cloud has a myriad of servers at different sites. Redundancy can be implemented to increase reliability and availability. The traditional computing systems rely on one or a few servers. Problems in these servers or even upgrading the servers may interrupt services. It is common that users of traditional computing systems receive messages from their system administrators that there is an interruption of services for a few hours because of maintenance. To ensure reliability and availability, conventional computing systems use redundant data centres. However, this is costly. A cloud computing service provider will definitely ensure high reliability and availability of its services as this is at the root of its credibility. In cloud computing systems, maintenance or server upgrades will not affect the services as they are addressed by other servers seamlessly.

The fourth benefit is *cost reduction*. Cost reduction on IT spending is highly expected as cloud computing can eliminate many conventional IT costs such as investment costs of hardware and software licenses as well as maintenance cost. As both investment costs and maintenance costs can be removed from IT spending, overall IT expenses in cloud computing is cheaper than conventional computing.

The fifth benefit is *scalable infrastructure*. In the cloud computing system, new hardware and new nodes can be added easily with limited modification to infrastructure setup and software

as the cloud architecture is designed to accommodate horizontal and vertical expansions. Also, the scale of the service can be expanded as requested. Hence, users can start with small and relatively inexpensive services and then expand the services as needed later.

The sixth benefit is *seamless upgrading and migration to new technology*. Technology, especially IT, keeps changing. It is hard to keep pace with the fast changing technology. However, it is important to keep updated with the latest technology as it helps improve computing performance. Updating to the latest technology is expensive and migration to a new system is not simple. Frequently, a migration requires a shutdown for a while, followed by a testing of the new system, which can create interruption of services. Upgrading and migration to new technology in cloud computing is seamless and the interruption of services is not necessary. Cloud computing providers normally keep their system up to date and the system update will have no implication for services.

Some Issues, Challenges, And Possible Outcomes

Although many advantages of cloud computing are discussed in the literature, there are many problems, issues and challenges as well such as issues on security, transparency and trust. We will discuss some issues, risks, and challenges of cloud computing shortly followed by possible solutions. Since the space is limited, we will only raise some important ones. We encourage the reader to find papers in the references or reading list for more related information.

Trust

The first and obvious issue is users (customers of cloud computing) lose control of their data. This can be a big hurdle for the adoption of cloud computing by both public and private organizations. With the conventional computing systems, all data and information are stored in the organizations'

server, policy of access on the data are established and enforced locally. Organizations make sure their information resources, especially data and information are protected from unauthorized access. Can organizations trust cloud providers to protect data on the same level of protection as if the data was stored locally? This is a very difficult question to deal with. Trust cannot be established easily, especially if there is no third party that can guarantee the security and privacy of data or information stored in the cloud. Everett (2009) discussed the issue of trust in cloud computing. One possible solution of this problem is to establish an assurance by an independent party through a certification or accreditation (such as ISO 27001 or SAS 70). An assurance from an independent third party can help establish trust between a provider and its customers.

Security

The second issue, which is highly related to the first issue, is security and privacy. This issue is also the issue of conventional computing, however, since users and their data are geographically separated and the users access the data through an open network such as the Internet, the issue highly affects the users' confidence in the cloud (Armbrust et al., 2010; Zhu, 2010). The security problems may happen in servers within the cloud, the client machines, and the network and each service model has its security issues. Subashini and Kavitha (2011) classify security issues on cloud computing into four categories: security related to third party resources, application security, data transmission security, and data storage security.

The security issues, especially on information security, can be systematically addressed using three components of information security: confidentiality, integrity, and availability (CIA). Confidentiality on data and information belonging to customers (users) is to protect the privacy of the data and information. Protecting privacy of data in conventional computing system is a technical challenge and the challenge is more complicated

in the cloud computing environment, which is distributed, and the customers are not aware of the location of data and access authorization. Sharing resources, although logically separated, if not taken care properly may pose another risk related to confidentiality of data (Badger et al., 2012).

There are some possible solutions on confidentiality of data. To keep the privacy of data, especially the sensitive ones, data must be stored in an encrypted form in the cloud storage. This may slow down data processing, as data need to be decrypted before processing. It is important to make sure whether the cloud provider has a strong encryption algorithm ready to be used. Otherwise, customers need to have their own encryption to protect their data. To avoid unintended loss of the logical separation of resource, customers may need to rest physical resource exclusively instead of rely on virtual machines allocated by the provider.

On the integrity of data or information (accuracy and consistency of stored data or information), cloud computing poses complex challenges. In a single standalone system, data integrity can be preserved by a database system through atomicity, consistency, isolation, and durability (ACID). The distributed nature of cloud computing makes data integrity a difficult issue (Abadi, 2009; Subashini & Kavitha, 2011) and cloud computing does not have assurance of data integrity. A new protocol that can solve data integrity on the cloud is needed. Kumar & Poornima (2012) proposes encoding data and data recovery that can ensure data integrity in the cloud.

Availability of data when needed is crucial. Just imagine what will happen when the data is needed for an urgent matter but the cloud is not available, neither applications nor data can be accessed. There are several possible causes of this problem; among others are attacks of denial of service (DOS), outage (including power failures, target of regulatory actions, or out of business), or simply storage problems in the cloud. Data redundancy and replication, including local replication of data can help to solve the problem.

There are some other issues on security. A survey on cloud computing security issues can be seen in (Subashini & Kavitha, 2011) and further discussion on security issues of cloud computing can be seen in (Jansen & Grance, 2011; Roberts & Al-Hamdani, 2011).

Lock-In and Interoperability

One of the business strategies of providers is to create switching cost to lock in customers so that they pay high prices to switch to another provider. Although interoperability among platforms may be supported by vendors, application program interfaces (APIs) for cloud-storage systems are proprietary and there is no standard for the APIs in the horizon (Armbrust et al., 2010; Marston, Li, Bandyopadhyay, Zhang, & Ghalsasi, 2011). According to Stallman (2008) customer lock-in on proprietary systems is a business trap since providers can change the price of the service at will. In the worst situation, the provider goes out of business, leaving customers wondering how to deal with their data stored in a proprietary format as the case of Coghead in 2009 (Marks, 2009). To avoid customer lock-in, standardization on APIs for storage systems is needed to allow interoperability among cloud providers.

Integration

It is highly likely that an organization will have multiple public clouds or hybrid clouds. Each cloud has its own data and APIs and the integration of applications or processes and data is needed. In addition, the existing legacy systems need to be integrated as well. Technology for such integration exists such as federated or heterogeneous database systems and enterprise application integration. These technologies can be adapted for the integration of clouds (Kim et al., 2009). There are many works to solve this issue; in fact some major vendors such as IBM and Oracle have offer their solutions, however, the complexity of the problem is not easy to solve as it may involve

other issues such security, scalability, management, and open platforms.

Performance

The distance between client machines and servers in the cloud and the network speed highly affect the performance of computation. The possibility of data transfer bottlenecks as the intensity of data processing and transfer as well as the number of users accessing the data increase may complicate the performance and costs as data transfer consumes the communication bandwidth (Armbrust et al., 2010; Kim et al., 2009). If the slow performance cannot be tolerated, the customers need to ask the provider to increase the bandwidth of data transfer. If we assume the provider can scale-up its infrastructure, the customer only incurs the additional cost for the scale-up. However, if the provider is unable to fulfill the demand as the scale-up may be beyond their expectations, things become complicated.

Disk access for data-intensive computation can be another source of performance problem as the I/O operation is much slower than CPUs and main memories (possibly shared by many virtual machines) and disks most likely shared by many users may cause unpredictable performance. Perhaps flash memory can be a solution, as the price is getting cheaper, consumes less energy and is much faster than disks (Armbrust et al., 2010).

FUTURE RESEARCH DIRECTIONS

Establishing trust between cloud providers and their customers is one of key success factors of cloud computing adoption. Trusted third parties can help increase the level of trust. Cloud computing governance model needs to be developed, as this can be used as a framework to strengthen the relationship a cloud provider has with its customers.

As the interest in the cloud computing is increasing and business in cloud computing is

growing, standardization of APIs and data format need to be developed to support interoperability and integration of the clouds. It can also remove vendor lock in impression. Perhaps XML data format is a good candidate for storing data in the clouds' storages as demonstrated by Knight (2009) in integrating Salesforce data.

The large penetration of small mobile devices (SMD) such tablet computers and smartphones globally has changed the way people interact and communicate. Users of these devices are connected to the Internet and they use cloud computing for many purposes, such as social networking, emailing, blogging, gaming, and storing information in the cloud storage. Mobile cloud computing is growing very fast most public clouds will be accessed by SMD. A recent survey in mobile cloud computing is discussed in (Fernando, Loke, & Rahayu, 2013). The integration of mobile and cloud computing is an interesting research area as it allows SMD to access powerful applications in the cloud.

Research on how education uses cloud computing so far and how cloud computing can support education will be very interesting, including mobile learning through the cloud and scientific research in the cloud. There are many opportunities created by cloud computing for education. Some cloud-computing vendors such as IBM and Google actively promote cloud computing as research tools and there are growing adoption of cloud computing by education institutions (Sultan, 2009).

Most of the APIs in cloud computing are proprietary and this raises concern of free/open source software communities. In fact, Richard Stallman (2008), the founder of Free Software Foundation, accused that cloud computing is another lock-in trap of proprietary systems with a different model. This accusation could be true as the APIs and data formats are proprietary as discussed above. Perhaps the open source community needs to create Open Cloud Computing fully supported by open source software using a grid computing model for the hardware connections.

CONCLUSION

Looking back at the development of IS technologies and methodology, it is apparent that the advent of cloud computing as it is today is a logical and inevitable advancement. We see that the ever-changing world of technology and globalization necessitates that businesses keep their information systems up to date and remotely accessible, and those who cannot keep up risk going out of business. Hence, the turn towards outsourcing their information systems to take advantage of a system that is scalable, never obsolete, secure and costs less.

The option to employ a cloud computing service, though, is not without its risks and questions. Will the data stored be secure from the likes of hackers and espionage? Can the providers be trusted with the privacy and sensitivity of the information? Can they keep their systems up to date? What if the provider itself goes out of business? Businesses must have full confidence in their providers before fully outsourcing their information systems.

Nowadays with smart phones becoming more and more powerful yet affordable, cloud computing will surely soon dominate, with desktops becoming less of a necessity. With the market for IS outsourcing in the hundreds of billions of dollars and expanding, more issues become apparent. Standardization must be established with regards to the data format and API's to prevent from customer lock-ins. This would in turn reduce the dependency of individuals and businesses on a single provider, reducing the risks associated with such a choice as outsourcing their IS.

The development of cloud computing is in full swing, and there is no question that as humans become more mobile and connected, the need for robust and secure cloud computing systems is becoming more important. Its vast effect on society is apparent in the popularity of web-based applications such as e-mail and social networking. New businesses want to setup their information systems to be web-based and accessible from thin

clients, and the developers of the web applications for these businesses want to develop their applications using computing resources in the cloud. For some, there is no choice but to employ a cloud computing solution. In fact, all must use a form of cloud computing in order to stay competitive in today's world, and this is the leading factor why it is predicted that the dominance of cloud computing will soon overtake desktop computers.

KEY TERMS AND DEFINITIONS

Cloud Computing: Is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g. networks, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.

Grid Computing: Is a middleware consisting of interconnected heterogeneous computer systems in a high-speed network to solve computation-intensive problems.

IaaS: Is a type of cloud computing service that provide infrastructure, especially servers or virtual servers located in data centers to customers. The servers or virtual servers are normally accessed through a computer network such the Internet.

Outsourcing: Is a business term to describe a mechanism in which a company utilizes services provided by another company, normally through a contract, to fulfill some of its required business resources or functions.

PaaS: Is a type of cloud computing service that offer the infrastructure as well as application development platform. PaaS providers accessible

through a computer network or the Internet provide all tools for development of applications. These tools may include automation in designing, deploying, testing, and administering applications to simplify application development.

SaaS: Is a type of cloud computing service that offer various software accessible to customers through the Internet.

Virtualization: Is mechanism to create virtual version of a real thing. Virtualization of a machine normally creates virtual versions of the machine, meaning several independent virtual machines for different purposes can be generated. In cloud computing, virtualization is used to generate virtual servers or virtual resources (such as storage) dynamically.

Improved Checkpoint Using the Effective Management of I/O in a Cloud Environment

INTRODUCTION

The emergence of cloud computing has brought a new dimension to the world of information technology. Although cloud computing offers several advantages such as virtualization, cost reduction, multi-tenancy, etc., there are risks and failures associated with it (Yang *et al.*, 2014). A key challenge for research in cloud computing is to ensure the reliability of the system without reducing the overall system performance. Among of fault tolerance, there is the strategy of checkpointing. The major problem of checkpointing is the overhead caused by the storage time of checkpointing files in stable storage, this time is estimated at 70% of checkpointing process time caused by the storage (Ouyang *et al.*, 2009a; Cornwell & kongmunvatana, 2011a), Figure1 shows the main phases of the checkpointing process. This process is based on three phases: i) suspend communication between processes and ensure consistent state; ii) use the checkpointing library to create and store checkpoints; iii) re-connect processes and continue execution.

The aim of our work is to minimize the overhead of checkpointing by minimizing its storage time. To ensure this goal, we improve the I/O management and we propose a checkpointing strategy of three phases:

1. The construction of VRbIO topology (Virtual RbIO): RbIO proposed in (Lui *et al.*, 2010) is

a virtual hierarchical topology; it minimizes checkpointing time and I/O time at the same time. In our system, each VM has a reactive agent responsible of the local I/O management; at the end of this phase some of these reactive agents will be activated to manage the I/O of a group of VMs of the server. In this case, the I/O will be hierarchical.

2. Creating the checkpointing files using co-ordinated checkpointing protocol.
3. Ensuring a lightweight and fault-tolerant storage of these files by using Collective and Selective Data Sieving input/output (CSDS I/O), which is executed by only the active agents. CSDS is an improved ROMIO I/O strategy. However, this strategy has several problems and limitations (Fu *et al.*, 2011).

Figure 1. The time of the phases of the checkpointing process

DOI: 10.4018/978-1-5225-2255-3.ch096

Our algorithm with its three phases provides solutions for most issues raised by the use of classical checkpointing with ROMIO as an I/O strategy. The rest of the chapter is organized as follows: Section 2 presents the background in the field of aggregating I/O techniques with a comparative study. ROMIO and its features are illustrated in Section 3. Section 4 presents our contribution, each service of this contribution is described in details, and all the problems cited in previous section are solved in this section. Section 5 presents some experimental results, followed by a conclusion and future research directions.

BACKGROUND

An important reason for the limitations of I/O systems is that applications often send smaller queries disjoint. This access mode generates a first additional cost to the large number of applications running on various transmission channels, but more significantly increases the processing time of the latter (Sadiku *et al.*, 2014). To deal with this problem, several “aggregation” methods have been proposed we can distinguish two types of aggregations strategies: dependent and collective.

Independent I/O is a straightforward form of I/O and is widely used in parallel applications. This form of I/O can be called independently by an individual process or any subset of processes of a parallel application. The advantage of independent I/O is that users have the freedom to perform I/O for each individual process or any subset of the processes that open the file.

The buffering is an Independent I/O (Cornwell & Kongmunvattana, 2011a). In conventional strategies, the write operation transfers data from the buffer to the local disk from their reception. Buffering proposes that the buffer will be used for temporary storage of I/O. The write operation includes small blocks in a buffer (of limited size). Once the buffer is completely filled, it will be forwarded to the local disk.

The “List I/O” approach (Thakur *et al.*, 1999a) provides routines to indicate within a single call access number. A list of torque (offset, size) describes the distribution of data in memory and a similar list is used to perform matching on disk.

Data sieving (Thakur *et al.*, 1999a) is one of the techniques proposed to address this issue by aggregating small requests into large ones. Instead of accessing each small piece of data separately, data sieving accesses a large contiguous scope of data that includes the small pieces of data. The additional unrequested data are called holes. The size of holes compared to the requested data controls the efficiency of data sieving.

For many parallel applications, even though each process may access several non-contiguous portions of a file, the requests of multiple processes are often interleaved and may constitute a large contiguous portion of a file together (Chen *et al.*, 2010). In order to achieve better I/O performance, a group of processes may cooperate with each other in reading or writing data in a collective and efficient way, which is known as collective I/O.

The collective I/O is a general idea that exploits the correlations among accesses from multiple processes of a parallel application and optimizes its I/O accesses. The basic idea behind this technique is to coordinate I/O accesses from different processors. The processors exchange information regarding what data each of them needs to access. This information is used to derive an efficient I/O schedule.

The collective I/O can distinguished by the “physical place” where the operation group is performed: if aggregation is executed among processes, the most used method is the “Two-Phase I/O” approach; if aggregation is performed at the records, we are talking about system “Disk-Directed I/O” if the approach is finally realized within a server, the method is “server-directed I/O”.

“Two-Phase I/O”, this method (Del Rosario *et al.*, 1993), as its name suggests, consists of two main phases: after a consensus between the

Table 1. Comparative study between aggregation techniques

Criteria	Data Sieving	Coll. I/O	ListI/O	ViewI/O	Buff
Useless Data Transfer	Yes	No	Yes	No	No
Network Data Transfer	Read: 1 Write: 2	2	1	1	1
Responsible	All	All	All	All	Manager
Resource	Local buffer	Local Buffer	Piggy-backed Message	Local/ Coll Buffer	Local/Coll Buffer
File Distribution	Logic	Logic	Logic\Physic	Logic\Physic	Logic

processes involved, the first step is to retrieve the data, the second concerns the redistribution between each of the latter processes.

To improve the I/O strategies (independent and collective I/O), the “File View” (Isaila *et al.*, 2003) proposes to specify the access patterns and reacts according to each model. The access pattern is defined according to the knowledge of Logical/Physical distribution of files in client and memory level.

ROMIO

ROMIO is one of the most famous I/O implementation, it combine between *Two phases Collective I/O* and *Data Sieving* to create contiguous requests

in node and system levels (Thakur *et al.*, 1999a). ROMIO three phases is observed:

- Independent requests, each process run independent requests to access a contiguous region of data.
- Create contiguous blocks using “Data Sieving” in each process.
- Collective I/O: processes communicate between them to collect contiguous blocks of the same file for different processes.

Figure 2 presents an example of ROMIO I/O in four processes. After phase ‘Read’ the Data sieving is applied in each process to create contiguous blocks. ROMIO does not use a common buffer and the data are distributed over the buffers

Figure 2. Example ROMIO (Chen *et al.*, 2010)

of different processes (number of aggregators = number of processes) (Chen *et al.*, 2010). In this case, the process should contact each other to create more contiguous. The contiguous requests for the same file.

The checkpointing using the ROMIO I/O management generally suffers from several problems such as:

- **Problem 1:** Expensive communication phase. The number of messages sent during the communication phase increases with the number of processes and the number of files blocks to read or write.
- **Problem 2:** Limited buffer of nodes. ROMIO is completely distributed, so the local buffers of processes are insufficient to store contiguous blocks.
- **Problem 3:** Quantity of unnecessary data can be high. ROMIO creates contiguous blocks by using Data sieving. It is possible that the holes beyond the useful data, which makes reading/writing expensive.
- **Problem 4:** The storage time is still high. Although ROMIO uses Data sieving and collective I/O to create contiguous blocks and eliminate duplicate blocks, and since ROMIO is completely distributed, each process will be blocked to achieve I/O.
- **Problem 5:** Files storing is not fault tolerant. To ensure the correctness of checkpointing, we must ensure the storage atomicity. The checkpointing with ROMIO is responsible for I/O without taking into account the atomicity.

Like other IT services, cloud services are not immune to failures. In addition in such systems the failure rate increases with the size of the system itself. In this context, the application of operational safety is an element of primary importance, so a fault tolerance mechanism is necessary to ensure certain aspects such as availability. The checkpoint is one of tolerance mechanisms most used in distributed systems failures. Our contribution is

proposed an approach for the management of I/O to minimize the time of checkpointing by reducing its storage time. In this work, we propose an adaptive checkpointing approach that solves each of these problems using a virtual hierarchic topology and a lightweight I/O strategy, we called CSDS (Collective and Selective Data Sieving) I/O and which ensures parallelism and scalability making it adequate to cloud computing.

CONTRIBUTION

The checkpointing time is divided into two parts: the overhead and the latency. Overhead checkpointing is the time necessary to ensure the consistency and capturing the current state of the system (Create checkpointing files). It depends on the used checkpointing protocol (coordinated, uncoordinated, induced communication,...). We have proposed a fault tolerant checkpointing strategy that provides a hierarchical storage without losing the notion of I/O parallelism and also improves the I/O management by a smart strategy CSDS.

System Model

Figure 3 shows the different services in the server. Servers (Physical Machine) are assigned to one or more virtual machines (VMs) using a hypervisor. The hypervisor is the software that provides a virtualized hardware environment to support running multiple operating systems simultaneously using a single physical server.

The server contains a topology constructor service and fault tolerance service. The objectives of these services are respectively: creating VR-bIO topology and providing fault tolerance using checkpointing protocol. (controlling checkpointing interval, ensuring checkpointing atomicity, ensuring a consistent state,...).

Each VM can accept an application for special user when executing an application. The kernel in the virtual machine contains the communication modules and task management. We have extended

Figure 3. Server architecture

this architecture by implementing a checkpoints module (CP module) inside each VM. CP module creates checkpoints file that saves the actual VM state. A reactive agent inside the VM is responsible of storing the checkpointing file created by the CP module. The colored boxes in each VM represent the buffers where the checkpointing files will be stored temporarily. The server is structured in virtual topology named VRbIO where the reactive agents inside VMs can be activate to manage an intelligent I/O of their server using CSDS modules (Collective and Selective Data Sieving). So CSDS module is activated only in case of active agent. We also assume that each data center contains a permanent storage memory where the checkpointing files will be stored. Only active agents have the right to write into the memory.

Algorithm of Our Approach

The algorithm consists of three main phases to ensure fault tolerance by checkpointing: Create a virtual topology VRbIO, create checkpointing files using coordinated checkpointing protocol then run CSDS I/O to store files in the stable storage server.

VRbIO Topology

ROMIO is a strategy completely distributed. So, all the nodes use their buffers for temporarily storing files. Then they communicate with each other to create more contiguous blocks (Collective I/O) which increases the time of communications phase. To solve this problem (problem 1), we propose to use a hierarchical topology for managing I/O. According to the comparative study of different

topologies proposed in (Lui *et al.*, 2010), it is clear that RbIO is the best topology that ensures the scalability and the parallelism. In RbIO there are two types of nodes: Worker and Writers. The Writer is the node responsible for managing I/O of a set of Workers. The Worker is an ordinary node; it belongs to a single writer on its server. RbIO proposed in (Lui *et al.*, 2010) is physical. However, in our work we will create a virtual fault tolerant RbIO named VRbIO in each server (Host). In our server, we suppose that each VM has a reactive agent responsible of managing the local I/O. In order to simulate the comportment of Worker and Writers of the physical RbIO, our VRbIO activates some reactive agents of the server to play the role of Writers. The other inactivated agents (reactive agents) will be Workers. The existence of reactive agents in all VMs and the activation process allow more dynamicity and flexibility in the architecture. When an active agent fails, it is sufficient to activate one reactive agent in its group, without any intervention. The activation of an agent means the activation of the CSDS service. Only the active agent can access to the stable memory to store the checkpointing files.

To create the VRbIO, the topology constructor of the server i selects at first γ_i reactive agents to be activated. We suppose that γ_i is equal to the square root of the number of VMs created in that server i . The list of VMs in server i is sorted in descending order of speed and buffer size. Starting from the beginning of the sorted list, the topology constructor activates the first γ_i reactive agents (the rest agents of the list remain reactive). The reactive agents are assigned to their active agents in a round-robin fashion (See Formula (1)). We note $AA_{k,i}$ as the active agent k in server i . so

$AL_i = \{AA_{0,i}, AA_{1,i}, \dots, AA_{(\gamma-1),i}\}$ is the list of active agents in the server i . The list of reactive agents is $RL_i = \{RA_{\gamma,i}, RA_{(\gamma+1),i}, \dots, RA_{n,i}\}$ where $RA_{j,i}$ is the reactive agent j in server i and n is the number of VMs in the server. We also define $G(AA_{k,i})$ as the list of reactive agents associated to the active agent $AA_{k,i}$ (the Workers).

$$RA_{j,i} \in G(AA_{k,i}) \Leftrightarrow k = j \bmod \gamma_i \neq 0$$

We note also $VM(RA_{j,i})$ as the VM of reactive agent j (and $VM(AA_{k,i})$ as the VM of active agent k). The VRbIO improves the checkpointing, When checkpointing interval expires, the $VM(RA_{j,i} \setminus RA_{j,i} \in G(AA_{k,i}))$ creates a checkpoint file (temporarily stored in the local buffer) then sends this file to its active agent $AA_{k,i}$. Upon the reception of checkpoints files, the $AA_{k,i}$ uses CSDS to improve I/O and minimize time storage of these files (See next section).

The fact that each reactive agent knows exactly its active agent, the communication time is reduced dramatically (problem.1). The problem with the strategy RbIO and even in ROMIO is the buffer size which may be insufficient to store checkpoints files (problem.2). In our approach, the VM of active agent (Writer) must be able to store the files of its group of VMs with reactive agents (Workers) to optimize I/O using CSDS. To consider this problem, we used an idea proposed in BlobCR (Nicolae & Cappello, 2011) strategy. According to this strategy, after the construction of VRbIO, each $VM(RA_{j,i})$ gives a part of the buffer to the VM of its active agent $VM(AA_{k,i})$. The Algorithm 1 gives the detail of VRbIO construction.

In Figure 3 that represents the server i , the list of active agents is: $AL_i = \{AA_{0,i}, AA_{1,i}\}$ where

$$\{VM(AA_{0,i}) = VM_1, VM(AA_{1,i}) = VM_2\}.$$

The list of reactive agent is: $RL_i = \{RA_{2,i}, RA_{3,i}, RA_{4,i}, RA_{5,i}, RA_{6,i}\}$ where $\{VM(RA_{2,i}) = VM_3, VM(RA_{3,i}) = VM_4, VM(RA_{4,i}) = VM_5, VM(RA_{5,i}) = VM_6, VM(RA_{6,i}) = VM_7\}$

For the group affectation, we have $G(AA_{0,i}) = \{RA_{2,i}, RA_{4,i}, RA_{6,i}\}$ and $G(AA_{1,i}) = \{RA_{3,i}, RA_{5,i}\}$

Checkpointing Creation

In our work, we used coordinated checkpointing. Where all VMs synchronize their efforts to create a consistent state using control messages. In a consistent state, orphan and transit messages are

Algorithm 1. The VRbIO construction

```

// $\gamma_i$ : Number of Active agents in the server  $i$ . //  $ListVM_i$ : The list of VMs in the server  $i$ .
//  $AL_i$ : List of active agents in the server  $i$ . //  $RL_i$ : The list of Reactive agents in the server  $i$ .
// Initiation
For  $j = 1$  to  $ListVM_i.size$  do
// All the agents in the VM list are reactive in the beginning
 $Agent(ListVM_i(j)).State = Reactive$ ;
 $RL_i.add(Agent(ListVM_i(j)))$ 
End for
 $\gamma_i \leftarrow \sqrt{ListVM_i.size()};$ 
 $ListVM_i$  sorted in descending order of speed and buffer size
// the activation of reactive agents
For  $j = 1$  to  $\gamma_i$  do
 $Agent(ListVM_i(j)).State = Active$ ;
 $Agent(ListVM_i(j)).ID = i - 1$ ;
 $RL_i.add(Agent(ListVM_i(j)))$ ;
 $RL_i.remove(Agent(ListVM_i(j)))$ ;
End for
For  $j = 1$  to  $RL_i.size$  do
 $RL_i(j).ID = (\gamma_i - 1) + j$ ;
End for
// The affectation of reactive agents to their active //agents
For  $j = 1$  to  $RL_i.size \neq 0$  do
For  $k = 0$  to  $AL_i.size \neq 0$  do
If  $RL_i(j).ID \bmod \gamma_i = k$  Then
 $G(AL_i(k)).add(RL_i(j))$ 
End If
End for
End for

```

avoided by blocking the communication during the checkpointing phase and storing the susceptible transit messages (Kangarlou *et al.*, 2012). In this case, the system stores a single recovery line in the stable memory. The coordinated checkpointing is used in several studies (Arockiam & Geo Francis, 2012), (Kangarlou *et al.*, 2012).

Fault tolerance service and topology constructor are responsible for selecting the checkpointing interval $Time_{cp}$ adequate to system features. If $Time_{cp}$ expires, the service informs its VMs by sending a request for checkpointing. Upon receiving this message, each VM creates its own checkpointing file (stored in local buffer). VRbIO topology allows us to use the technique of Soft checkpointing. In conventional strategies (Hard checkpointing) VMs store their files directly in the stable memory which increases the storage time (Chen *et al.*, 2010).

In our strategy, each $VM(RA_{j,i} \setminus RA_{j,i} \in G(AA_{k,i}))$ sends its checkpoints file to $VM(AA_{k,i})$ and then continues immediately the execution. The $AA_{k,i}$ is responsible for storing the files of its reactive agent's VMs in the stable memory. This hierarchical checkpointing storage is called Soft checkpointing and it is a solution for the problem 4.

The major problem in the checkpointing is to ensure its atomicity, that is to say, we must ensure that all concerned VMs complete the creation of their checkpointing (create the file checkpointing and stored). In our approach, the active agent ensures partial checkpointing atomicity of the VMs of its group of reactive agent including its VM. If during the checkpointing, a $VM(RA_{j,i} \setminus RA_{j,i} \in G(AA_{k,i}))$ is incapable of creating its checkpoint (this is the case of a failed VM, blocked VM, busy VM, ...), its reactive agent $AA_{k,i}$ will be informed (either by a special message, fault

Figure 4. Checkpointing management

detection service or even a timeout). In this case, $AA_{k,i}$ cancels the checkpointing of VM in $G(AA_{k,i})$ by sending a message “Delete” to them (VMs that have not yet send their checkpointing file) and to the other active agents in AL_i of its server i . If a $AA_{j,s} \setminus s \neq i$ receives “Delete” from $AA_{k,i}$, it cancels the checkpointing of its $G(AA_{k,i})$. This partial atomicity technique solves the Problem 5 and makes the checkpointing itself fault tolerant. After the $AA_{k,i}$ collects checkpointing files of its $G(AA_{k,i})$, it uses the CSDS service to optimize the I/O (See Figure 4).

CSDS for Checkpointing Storage

After the $AA_{k,i}$ ensures checkpointing atomicity of its group, its CSDS service handles the I/O management to minimize the checkpointing latency. CSDS is similar to ROMIO. But in ROMIO, the Data Sieving and collective I/O will always be executed regardless of the size of useless data quantity caused by Data Sieving (Holes). In this case, the amount of unnecessary data can be large

compared with the useful data, which increases the cost and the time of the I/O (problem 3). To resolve this issue, the CSDS of the active agents $AA_{k,i}$ executes Collective I/O for data requested by different $VM(RA_{j,i} \setminus RA_{j,i} \in G(AA_{k,i}))$, and then performs Data Sieving only if the size of useless data UD_j does not exceed a certain threshold α_j versus the total size of data to be written D_j by the active agent j . The threshold α is specified by SLA criteria (System Level Agreement).

The β_j parameter of active agent j represents the percentage of useless data written relative to the entries data (see Formula 2). The β_j will be compared to α_j to decide to perform a Data Sieving or not (simple buffering).

$$\beta_j = \frac{(100 \times UD_j)}{D_j} \quad (2)$$

This strategy eliminates the problem 3. The details of CSDS algorithm executed by an active agent $AA_{k,i}$ are illustrated in Figure 5.

Figure 5. CSDS Algorithm

EXPERIMENTAL RESULTS

Our approach noted CP_CSDS is destined to improve the checkpointing performances and it uses CSDS to manage the I/O, so we compare it with a classical coordinated checkpointing using ROMIO as I/O strategy (CP_ROMIO). We used several scenarios and parameters and we implement the

approaches in CloudSim simulator (Calheiros *et al.*, 2011).

In the first experiment, we measured the storage time of checkpoints files (checkpointing latency) in both I/O strategies using a server of 10 to 20 VMs and a checkpointing interval=10 minutes. The results are presented in Figure 6. CP_CSDS reduces the storage time of checkpoints files by a

Figure 6. Impact of number of checkpoints on storage time

Figure 7. Impact of checkpoints sizes on storage time

Figure 8. Impact of number of nodes involved in the checkpointing on storage time

most 30% compared to CP_ROMIO. CP_CSDS uses VRbIO to reduce the communication phase. This is due to the hierarchical checkpointing storage used by RbIO and the I/O management based on CSDS that reduces the communication phase.

The second experiment is destined to measure also the storage time in case of different sizes of checkpointing files. According the results illustrated in Figure 7, the storage time increases if the size of files increases. However, our strategy CP_CSDS is better than CP_ROMIO (a gain of 20%) because the CSDS reduces the transfer of useless data during the I/O.

The purpose of the third experiment is to study the scalability of our strategy in terms of number of participating nodes in checkpointing

process. From the results shown in Figure 8, increasing the number of participating nodes in the checkpointing automatically increases the storage time in the classical approach of CP_ROMIO. In CP_ROMIO, all the nodes must communicate with each other to ensure the “Collective I/O” phase. In our approach CP_CSDS, the topology VRbIO provides a load balancing and scalability. Just the active agents communicate with each other to ensure the I/O which greatly reduces the storage time. The gain in term of storage time is $\approx 30\%$ compared to CP_ROMIO.

The last experiment calculates the overhead caused by the checkpointing using both approaches I/O (See Figure 9). It is clear that our approach CP_CSDS reduces significantly the

Figure 9. Impact of number of checkpoints on the Overhead

overhead of checkpointing ($\approx 18\%$) because in addition to reducing the storage time, it uses the soft checkpointing.

CONCLUSION

Checkpointing is very powerful fault tolerance technique in term of fault management and can be used for different objective such as migration and load balancing. The major problem of this technique is the storage time which can increase response time and minimizes the possibility to meet the deadlines specified by the user and the SLA rules. To improve the performance of checkpointing in the clouds, we have focused in this paper on minimizing the storage time of checkpointing files in stable storage server. Our approach involves three main steps: the construction of the virtual topology VRbIO, creating checkpointing

files using coordinated checkpointing protocol and finally save these files in the stable memory using a new strategy I/O that combines between the collective I/O and intelligent data sieving CSDS. In this paper we explained the various problems of using checkpointing with ROMIO as I/O strategy (CP_ROMIO). Our approach solves the majority of classical problems and makes the checkpointing appropriate for clouds environment. A brief comparison between our approach CP_CSDS and that of checkpointing with ROMEIO I/O (CP_ROMIO) is presented in Table2. In this table, the parameter n presents the number of nodes (VMs) in the server.

FUTURE RESEARCH DIRECTIONS

Several directions can be exploited, we can mention:

Table 2. CP_ROMIO vs CP_CSDS

	Topology	Number of Writer	Flexibility	Type of Checkpointing	Communication Phase	Buffer Problem	Transfert of Useless	Atomicity
CP_ROMIO	Distributed	n	No	Hard	Yes	Yes	High	No
CP_CSDS	Hierarchical (VRbIO)	$\sqrt{n}$	Yes	Soft	No	No	Reduced	Yes

- Improve strategies of VRbIO topology by making the assignment of workers (reactive agents) to their writers (active agents) dynamic depending on the load and the characteristics of the system;
- Improve CSDS by the choice of other critical criteria to swing between the transfer block and the data Sieving as: i) data transfer time; ii) energy consumption; iii) the cost.
- Extend CSDS in a predictive system by pre-loading for user checkpoint file playback which minimizes recovery time in case of failures.

KEY TERMS AND DEFINITIONS

Cloud Computing: Refers to applications and services offered over the Internet. These services are offered from data centers all over the world, which collectively are referred to as the “cloud”.

Checkpointing: A technique to add fault tolerance into computing systems. It basically consists

of saving a snapshot of the application’s state, so that it can restart from that point in case of failure.

Collective I/O: In many parallel applications, despite the fact that each process may need to access several noncontiguous portions of a file, the requests of different processes are often interleaved and may together span large contiguous portions of the file. Collective I/O procedure is used to improve significantly the I/O performance by merging the requests of different processes and servicing the merged request.

Data Sieving: To reduce the effect of high I/O latency in parallel applications, it is critical to make as few requests to the file system as possible. Data sieving is a technique that enables an implementation to make a few large, contiguous requests to the file system even if the user’s request consists of several small, noncontiguous accesses.

ROMIO: A portable MPI-IO implementation that works on many different machines and file systems.

Service Quality and Perceived Value of Cloud Computing–Based Service Encounters

C

Eges Egedigwe

Dallas County Community College, USA

INTRODUCTION

Cloud computing based technology is becoming increasingly popular as a way to deliver quality education to community colleges, universities and other organizations. At the same time, compared with other industries, colleges have been slow on implementing and sustaining cloud computing services on an institutional level because of budget constraints facing many large community colleges, in addition to other obstacles. Faced with this challenge, key stakeholders are increasingly realizing the need to focus on service quality as a measure to improve their competitive position in today's highly competitive environment. The purpose of this article is to present a study that examined the expectations and perceptions of instructors' usage of cloud computing based technology on overall quality of service (QoS). The article explores literature review that establishes the rationale and framework for this investigation, research methodology, data analysis, and results. A final section will include a summary of the findings, conclusions, and recommendations from the study.

BACKGROUND

Cloud Computing Environments

The explosive growth in computer usage by business, government, educational institutions, combined with global collaboration provided by the Internet, and competition has brought a considerable increase towards computer usage along

with the associated need to maximize the use of available resources while minimizing costs. One area of growing interest for meeting these needs is the use of cloud computing to centralize computing and information management functions for large, often geographically dispersed organizations. Users only need to pay for the services they actually use (Kim, Kim, Lee, & Lee, 2009). It offers potential benefits related to reductions of server/storage infrastructure and delivery of services (Leavitt, 2009). Some of the primary types of cloud computing services include infrastructure as a service, platform as a service, and software as a service (Leavitt, 2009; "National Institute," 2011). Leavitt (2009) also included a general group called services, which consist of storage, middleware, collaboration, and databases provided via the Internet. These technologies and services together comprise the majority of the types of computing services available from cloud computing, ranging from hardware and software services, to entire computing environments. Cloud computing offers potential benefits related to reductions of server/storage infrastructure and delivery of services (Kim et al., 2009; Robinson, 2009). Cloud computing can be highly beneficial in educational settings. Among the possible benefits is the enhanced usefulness of the existing technology (Erenben, 2009). With its emphasis on the delivery of low-cost or free applications anywhere on the Internet, cloud computing is a promising prospect for educational institutions faced with budget restrictions and mobile student population (Denton, 2012). This study builds on the SERVQUAL model, discussed next, to analyze

DOI: 10.4018/978-1-5225-2255-3.ch097

the significance of expectations and perceptions of instructors' usage of cloud computing technology in community colleges.

SERVICE QUALITY MEASUREMENT

According to Renganathan (2011), quality is a subjective concept that has no generally agreed definition for it. The word quality means different things to people according to the context. In general it is difficult to measure and quantify service quality. The main purpose of measuring service quality is to ensure whether service is provided as per the expectations of the customers. There are several well-known tools for measuring service quality or customer satisfaction. The most eminent instrument in attempting to systematize the service quality is "The gap model" of service or SERVQUAL developed by Parasuraman et al. (1985). This conceptual framework was developed initially to measure customer perception of service quality for the financial service sectors but later extended to sectors such as hospitality, telecommunications and healthcare. The SERVQUAL's model, which was developed by Parasuraman et al. (1988) used a survey to ask respondents for an indication of their expectations as well as their perceptions of service, and establishes the gap between the two. Other researchers, such as Cronin and Taylor (1992), held that only the perception of quality is important. The next section highlights how SERVQUAL has been used in universities to assess satisfaction not only with teaching and

learning, but with support services such as information technology (Smith et al., 2007).

MEASURING SERVICE QUALITY IN HIGHER EDUCATION

Frequently, higher education institutions seek to provide high quality services in all parts of their educational curricula and administrative processes. Therefore, the importance of service quality makes its measurement and its subsequent management an issue of utmost importance (Shekarchizadeh, Rasli & Hon-Tat, 2011).

The review of literature shows that some studies used the SERVQUAL model to measure service quality in higher education. Boulding, Kalra, Staelin, and Zeithaml (1993) used SERVQUAL model to study expectations and perceptions linked with the delivery of services in an educational environment. Their study used SERVQUAL to measure students' satisfaction with overall quality of service in a higher educational setting (Al-alak & Alnaser, 2012). Table 1 below shows hypotheses' testing results of their study. All but the sixth hypothesis was accepted. Hampton (1993) also used SERVQUAL model to measure college student satisfaction with professional service quality. In examining students' perceptions of service delivery, he applied the gap model (the disparity between expectations and experiences). These studies support the use of SERVQUAL model to measure instructors' usage of cloud computing technology

Table 1. Hypotheses' testing results

Source: Schwantz, 2012, p. 161, Table 4

Another study that supports the use of a modified version of SERVQUAL in academia to measure student satisfaction of the service they received was done by Schwantz (1996). Schwantz modified the usage of SERVQUAL instrument to make the comparison between traditional and non-traditional students' views of the quality of service in one higher educational institution. Students were asked to compare the quality of service (expected and received) of the support staff with that of faculty members. Based on factor analysis, the researcher identified the dimensions of the instrument where he used two dimensions instead of five, which are acknowledged by Parasuraman, Zeithaml and Berry (1990). The outcome of this study revealed no significant difference in the expectations or perceptions of traditional versus non-traditional students. There were no significant differences in students' expectations for support staff versus faculty. However, there was a significant difference in the students' perceptions of service quality from support staff versus service quality from faculty.

Other studies have borrowed some of the dimensions of SERVQUAL model to investigate the impact of a number of service quality attributes on satisfaction and loyalty in a higher education setting. Investigating the differences in student satisfaction and identifying dimensions of overall perceived quality, a study by Ong and Nankervis (2012) revealed that students with different academic performances perceived the impact of quality attributes on satisfaction differently compared with students with lesser performances. It was also shown that differences in overall satisfaction with educational experience were found among different lines of specializations. Drawing concepts from services marketing and assessment literature, Duque and Weeks (2010) developed a conceptual model to assess student learning outcome. It was found that student perceptions of educational quality had a noticeable impact on student satisfaction.

There has also been considerable research to re-examine the reliability and validity of SERVQUAL

(Asubonteng, McCleary & Swan, 1996; Brown, Churchill & Peter, 1993; Ladhari, 2008; Lam, 1997; Shahin, 2004). Ladhari (2008) suggested that industry-specific measures of service quality might be more appropriate than a single generic scale. He then encouraged researchers and scholars toward the development of an alternative industry-specific research instruments for measuring service quality. Lam (1997) found that the results are consistent with those reported in Babakus, Boller (1992), and Parasuraman et al. (1996), suggesting that both measures exhibit desirable levels of reliability and internal consistency. This view was echoed by Asubonteng et al., in their 1996 research: that SERVQUAL will predominate as a service quality measure.

Summarizing, although, SERVQUAL has been proven to be a reliable instrument for measuring expectations and perceptions of service quality (Parasuraman, Zeithaml & Berry, 1990; Parasuraman, Zeithaml & Berry, 1994) and most of studies have focused on students' satisfaction with overall quality of service and/or with professional service quality in high education. But the literature review reveals the lack of studies on instructors' satisfaction with cloud computing technology in educational settings. This study fulfils this need. The next section will describe the methodology used for the study followed by the reliability and validity of survey instrument and data analysis.

METHODOLOGY

The current study involves the use of a quantitative method to collect and analyze data received from the sample population regarding instructors' perception of the service quality provided by cloud computing based system in large community colleges in Texas. The use of quantitative methods ensure the current study is specific and narrow, whereby the researcher can uncover measurable, observable data on the variables. Quantitative research enables the collection of data from instruments with preset questions and responses, and

Table 2. Reliability analysis

CONSTRUCTS	Number of Items	Cronbach Alpha (α)

PAS (Service Quality Perception on Assurance)	5	0.982
PEM (Service Quality Perception on Empathy)	5	0.972

acquire data from a large population (Creswell, 2005). The study identified one primary research question that was used to guide this investigation, which is: Do the difference between instructors' perception and expectation significantly affect their perceived service quality of cloud computing based systems? The study collected and analyzed data based on the above research question from large community (or two year) colleges in Texas.

The target population for this study comprised of instructors or faculty members (referred to as 'participant') with sufficient experience using cloud computing technology in two year colleges in the State of Texas. Subjects were drawn mostly from faculty members' of three large community colleges (Dallas County Community College District (DCCCD), Houston College System (HCS), and Lone Star College System (LSC)) in Texas that provided Institutional Review Board approvals. The sample size is determined based on the size of the target population and the desired accuracy of the study. The target population is 11,395. A random sample of 470 email addresses of faculty were selected from the target population using the "Random Numbers Generator" feature of the SPSS statistical package. All the 470 instructors that were randomly selected received an online survey hosted by SurveyMonkey.com.

The model for this study leverages service quality (SERVQUAL) multi-item scale developed to

assess customer perceptions of service quality in service and retail businesses (Parasuraman et al., 1988). The scale breaks down the notion of service quality into five dimensions identified through this process and assessed using 22 item scale: Tangibles - physical facilities, equipment, staff appearance, etc.; Reliability - ability to perform service dependably and accurately; Responsiveness - willingness to help and respond to customer need; Assurance - ability of staff to inspire confidence and trust; and Empathy - the extent to which caring individualized service is given. Survey questions were designed based on the 22 questions of SERVQUAL. Some modifications to the wording were made to make them relevant to the cloud computing based environment.

RELIABILITY AND VALIDITY OF SURVEY INSTRUMENT

The reliability of each of the SERVQUAL's dimensions was assessed using Cronbach (1951)'s alpha as depicted in Table 2 - Reliability Analysis. The survey was also pre-tested for its reliability (Nunnally & Bernstein, 1994; Straub, 1989). Reliability in this context is the extent to which a measurement procedure is free from error. The estimation of alpha under the different number of items were examined using SPSS. The reliability coefficient

(Cronbach's alphas) for all the constructs ranges between 0.869 - 0.982. This supports reliability and face validity for the SERVQUAL scores for all the constructs.

The survey did not require personally identifying information. Anonymity was guaranteed by instructing participants to avoid placing their name, return address, or any identifying information on the survey. Strict controls over all data collected were maintained by not sharing the responses from any participants. Once the data was collected and downloaded, a Likert-scale type result spreadsheets/database of the survey instruments was generated. A codebook was built for this study describing each independent, dependent and other variables used in the data analysis. The responses to the variables were entered into the statistical applications software package - Mplus version 7.3 and IBM Statistical Package for the Social Sciences (SPSS) v22 – used for analysis.

DATA ANALYSIS AND RESULTS

According to Marshall and Rossman (1995), “Data analysis is the process of bringing order, structure, and meaning to the mass of collected data. It is a messy, ambiguous, time-consuming, creative, and fascinating process” (p.111). The survey responses from 301 participants were analyzed

using a mixture of statistical approaches in an effort to provide order, structure, and meaning to the survey data collected. Data was scanned for univariate and multivariate outliers, defined as values that are greater than 3.29 standard deviations from the mean (Stevens, 2009). Three participants were removed for being multivariate outliers. Another 46 participants were removed from the data collected for not completing major sections of the survey. A random sample of 470 potential participants was selected. From those, 301 participants (64%) took part in the study. Data analysis was conducted on 252 participants (54%) after removing sixteen (16%) percent of those responses that were incomplete or unusable.

The analysis of the data was reported using the research questions as a foundation. The analysis plan of hypothesis testing is shown in Table 3. The statistical data were analyzed using descriptive statistics (frequencies and percentages, mean, standard deviation, skewness, and kurtosis) and inferential statistics (correlation, shared covariance, structural equation modeling (SEM), and ANCOVAs). Descriptive research answers the questions of who, what, where, when, and how; however, it is not used to create a causal relationship (Gay, 1992). Table 4 presents the descriptive statistics for the expected, perceived, and differences scores.

Table 3. Analysis plan of hypothesis testing

Number	Hypothesis	Statistical Test
RQ1: Do the difference between instructors' perception and expectation significantly affect their perceived service quality of cloud computing based systems?		
H ₀₁	The difference between expectation and perception of reliability will not significantly load onto perceived service quality of cloud computing based systems - (DRL).	SEM & z-test
H ₀₂	The difference between expectation and perception of assurance will not significantly load onto perceived service quality of cloud computing based systems - (DAS).	SEM & z-test
H ₀₃	The difference between expectation and perception of tangibles will not significantly load onto perceived service quality of cloud computing based systems - (DTN).	SEM & z-test
H ₀₄	The difference between expectation and perception of empathy will not significantly load onto perceived service quality of cloud computing based systems - (DEM).	SEM & z-test
H ₀₅	The difference between expectation and perception of responsiveness will not significantly load onto perceived service quality of cloud computing based systems - (DRS).	SEM & z-test

Table 4. Descriptive statistics for expected, perceived, and difference scores

Score	Min	Max	M	SD	Skewness	Kurtosis

DEM	-3.00	3.80	0.42	1.04	0.82	1.60

Prior to assessing the research question, the model fit of the empirical model (Figure 1) was examined through structural equation modeling (SEM) for goodness-of-fit. SEM was used to determine the model fit. Perceived quality of service (PSQ) is not a measured construct, and thus regression analysis is not possible. PSQ is a first order latent variable made up of the differences between expectation and perception of reliability, assurance, tangibles, empathy, and responsiveness.

To have a good model fit, the model should have a non-significant χ^2 statistic. However, since the χ^2 statistic can be unreliable for larger sample sizes, additional fit indices were also examined for to determine model fit (Kline, 2005). The comparative fit index (CFI) should be above 0.90. The root mean square error of approximation (RMSEA) should be below 0.10. Due to poor model fit, $\chi^2(5) = 32.36$, $p < .001$, CFI = .94, TLI = .88, RMSEA = .15, modification indices were examined to assess how the model can be improved empirically.

Modification indices provided ways to empirically improve the model. If the changes make theoretical sense, then the modification indices was tracked to improve the model to fulfill the requirements for a good model fit (Kline, 2011). Using SPSS, a statistical program, a correlation matrix was calculated to estimate the relationships among all the variables (i.e., between all possible pairs of variables) as shown in Table 5 - Correlation Matrix. The correlation for all paired variables are “statistically significant” at the 0.01 level (2-tailed).

In order to address research question 1 and hypotheses 1 – 5, structural equation model (SEM) (a confirmatory factor analysis (CFA)) was conducted to assess if the DTN, DRL, DRS, DAS, and DEM variables loaded onto the single perceived service quality (PSQ) latent construct. The data was entered into MPlus for analysis. The results provided a good model fit for the data, $\chi^2(4) = 15.01$, $p = .004$, CFI = .98, TLI

Figure 1. Conceptualization of model to be tested. Paths between expectation and perception represents the differences between these values

$=.94$, $RMSEA = .10$. Because the good model fit was found, the individual factor loadings for each of the variables was examined in order to address the research questions. The standardized estimates for the factor loadings were examined to determine the significance of each indicator. All indicator variables had a p value that was less than .001, thus showing significance. Because significance was found for each of the variables, null hypotheses 1 – 5 were all rejected in favor of the alternative hypotheses. Table 6 presents the results of the confirmatory factor analysis. Table 7 presents model fit information for the original

and modified models. Table 8 presents that results of hypotheses 1 – 5 tested. The next section will discuss future research directions.

FUTURE RESEARCH DIRECTIONS

The current study attempted to investigate instructors' perception regarding the service quality provided by cloud computing based system in large community (or two year) colleges in Texas as expected. Hence, it would be beneficial for future research to consider the following suggestions:

Table 5. Correlation matrix

1. Further studies using the same methodology for the same population to examine the long-term implications of service quality improvement efforts.
2. Expansion of the study to include all two year colleges and not just large community colleges in the state to establish competitive benchmarks, track defections to other clouding computing providers caused by poor service delivery, and promotes a statewide service quality measurement and instructors satisfaction.
3. Evaluation can be made on the most common service quality measurement instruments in higher education. A comparative study will also be useful in this domain.
4. Additional exploratory, qualitative, and empirical research on the impact of instructor satisfaction vis-à-vis the wide variety of instructor demographic variables.
5. Further studies of the many types of service encounters, including service failures and recoveries, present in higher education.
6. An extension and testing of a model to measure internal customer satisfaction between service providers and institutional departments.

CONCLUSION

This study of instructor perceptions of service quality and perceived service quality (or satisfaction) of cloud computing technology in large community colleges in the State of Texas yielded support for the model tested, and expanded on previous service quality research in business and higher education. The findings of the study added inputs to the body of knowledge in higher education in Texas. Therefore, it is hoped that other colleges/universities will replicate the implications of this study.

It is quite evident that service quality has significant positive relationships with instructors' satisfaction based their continued use of cloud computing technology. Thus, instructors' satisfaction level can be enhanced by improving the service quality which confirms with the findings of other research work. This is critically important as community colleges have to compete with other higher academic institutions to serve the interests of the students. The results of the hypotheses tests are presented in Table 8. The results indicated that the differences between the expectation and perception on all five SERVQUAL dimensions load to the instructors' perceived service qual-

ity. Institutions should be held accountable for effectively meeting or exceeding instructors' expectations of the quality of services it provides.

KEY TERMS AND DEFINITIONS

Cloud Computing Based Technology (or System): Includes information technology services and capabilities that are perceived as useful and accessible, which enable the users to provide beneficial services via technological interfaces.

Expectation (E): The performance anticipated or expected by the consumer. They form the reference point against which product or service performance is compared.

Perception (P): The customer's judgment about the service encounter – the actual service received.

Provider: An organization supplying cloud computing resources to outside users.

Service Quality or Perceived Service Quality (PSQ): Service quality is defined as the customer's perception of the level of success or failure in meeting expectations (P-E).

User: An organization or individual that uses cloud computing resources as a customer of a cloud computing provider.

Understanding Business Models on the Cloud

Arash Najmaei

Australian Catholic University, Australia

INTRODUCTION

The relationship between business models and technologies is an increasingly important issue. New technologies instigate new business models and new business models enable commercialization and success of new technologies. Building on this notion, this chapter synthesizes the literature on business models and cloud computing- a relatively new information technology- It shows that the relationship between business models and cloud-based systems create two distinctive technological trajectories: 1) cloud computing as a business model which can be seen as the development of cloud computing business models' (hereafter CCBM) and 2) cloud computing-enhanced or enabled business models which can be broadly thought of as traditional business modeling with improvements using cloud computing (hereafter BMCC). The former refers to a technological model or a system that commercializes value created solely by cloud-based systems in public and private sector. Whereas the latter refers to various ways that cloud-based systems can be and have been integrated into existing business models to enhance improve or enable creation and commercialization of new value. An explicit acknowledgement of these two trajectories and their underlying architecture are remarkably absent in the literature. Therefore, discussion outlined in this chapter is a timely contribution to the growing body of knowledge on how and why cloud-computing matters as a revolutionary technology.

The chapter proceeds as follows: first an overview of the concepts of business model within the framework of technology management is offered

in order to outline where the business modeling stands with respect to cloud computing as an emerging technology. Then cloud computing as an emerging technological paradigm will be discussed. Next, the architectural and structural ways through which business models and cloud computing systems are integrated will be illuminated in terms of two technological trajectories as briefly outlined above. Finally, the chapter concludes with a discussion on the implications of this conceptualization for theory and practice.

BACKGROUND

Technologies are developed to provide solutions to the problems humanity face. One of the most striking characteristics of our era is the exponential growth in the amount of information produced and the consequential need to process and store it. Information technologies refer to a family of technologies that solve such problems by enabling us to systematically collect, storage, clean, organize (mine), analysis, transform and present (visualization) information to satisfying our evolving needs.

Technologies do not emerge in vacuum. Their development is based on a purposeful orchestration of resources and application of knowledge. Business models play a fundamental role in this process. A business model defines the purpose of the technology and determines how resources are configured and orchestrated to bring the technology into the market (Chesbrough & Rosenbloom, 2002). When a technology is brought into the market it opens new avenues to develop new busi-

ness models (Teece, 2010). This interplay pushes the technological frontiers forward, makes old technologies obsolete and creates demand for new technologies (Najmaei, 2012, 2014b). Let's look at the information technologies as an illustration of this process. The traditional and still prevalent business model of ITs is based on investment in infrastructure. Simply said, if one needs to store and process data one has no choice but to buy or build a datacenter and a server to get these tasks done. This business model has worked well for years, and evolved into a global cluster of industries that offer advanced tools, systems and models all requiring heavy upfront investment and ongoing maintenance. In addition, technologies to process and store information are not easily available when we need them, where we need them.

Cloud computing (CC) is a technology developed based on a radically different business model aimed at solving these problems. It is a revolutionary approach to the provision of information technologies and radically changes the traditional business model of IT. CC offers a new way to make information technologies available to those individuals and organizations who demand it, when they need it, and where they need it by reducing the need for initial investment, hosting and ongoing maintenance (Hayes, 2008).

The idea behind CC is to bring the long-held dream of IT as a utility into life (Armbrust et al., 2009). CC is not only based on a new business model but also has a great potential to enable many new business models and radically change existing ones (Chang, Bacigalupo, Wills, & De Roure, 2010; DaSilva, Trkman, Desouza, & Lindic, 2013; Khanagha, Volberda, & Oshri, 2014; Lindgren & Taran, 2011; Weinhardt et al., 2009).

The constant interaction between existing and new technologies and business models epitomizes an evolutionary process which can be called technological business modeling (Najmaei, 2014a; Najmaei, Rhodes, & Lok, 2015). Drawing on this analogy, this chapter posits that the interplay between cloud computing and business models creates two distinctive technological trajectories

each with important theoretical and practical implications: 1) the business modeling with cloud computing and 2) the cloud computing business model. The insights from the literature on technological paradigms, clusters and trajectories will be used to develop this argument.

CLOUD COMPUTING, BUSINESS MODELS AND TECHNOLOGICAL PARADIGM

As noted, technologies are developed to solve problems. In doing so each technology follows a specific paradigm. A technological paradigm is a model or pattern of solution of selected technological problems (Dosi, 1982). Technologies related to each other in a given paradigm form technological clusters (Dosi, 1982). Technological clusters such as nuclear technologies, biotechnologies, semiconductor technologies and information technologies are, hence, a group of technologies sharing the same paradigm and addressing similar problems (Dosi, 1982). Technologies advance and evolve within a cluster along technological trajectories. A technological trajectory is the pattern of normal problem solving activity on the ground of a technological paradigm (Dosi, 1982). These trajectories represent evolutionary directions of technological changes within a paradigm until a paradigm shift takes place when paradigms collapse, change, merge or new paradigms emerge (Dosi 1982).

Technological trajectories and paradigms are closely related to business models (Teece, 2010). A business model is a logic or a set of assumptions that determines how well a technology fits in the market (Chesbrough & Rosenbloom, 2002). Technologies are brought to the markets when there is a demand for them. A market for a given technology is a place where users of the technology meet its sellers to exchange the rights to own and/or use the technology. This exchange can't happen without a business model in place. Therefore, a business model as a model is a sim-

plified representation of reality of the technology in a particular paradigm to be realized the market on a specific trajectory (Najmaei, 2014b). Take for example, online social networking technology. Business models of companies such as Facebook, Snapchat, WhatsApp and Twitter all represent a simplified reality of social networking on the web using firm-specific technologies which are all in one paradigm but evolving along different trajectories. The specific business models they use enable us to differentiate them from one another and at the same time relate them to each other. For a technology-developer or techno-preneur such as business model is essentially a mind-set or simply a blue print that describes how a technology creates value for its users and captures value for its sellers in an identifiable manner (Zott & Amit, 2013; Zott, Amit, & Massa, 2011). For a technology user such a business model is a means to place a business in a paradigm along a trajectory. Therefore, a business model is a bridge between suppliers of a given technology and its buyers. A well-functioning business model performs this functions by defining how a technology attracts buyers by showing them how it creates value and provides impetus for sellers by telling them how it is commercialized to capture its value. Both value creation and value capture are based on the assumptions of the paradigm within which the core technology of the business model is situated.

More specifically, creation of value refers to the way the business model uses the technology to offer new benefits, enhance execution of some hitherto difficult or complicated tasks, or to present an improved utility for users of the technology by simplifying jobs and solving problems at hand more efficiently (Bowman & Ambrosini, 2000). Creation of value is captured by the concept of 'use value' (Bowman & Ambrosini, 2000) which refers to the perceived usefulness of the technology by its users.

When value is created it should be captured as well. Capturing value refers to how a technology is commercialized in the market place in order to cover its costs and create profit by convinc-

ing users to pay for it (Bowman & Ambrosini, 2000). Value capture is tied to the profit formula associated with the technology and is simply represented by the concept of exchange value. That is the monetary value exchanged between seller and buyer for the use of the technology (Bowman & Ambrosini, 2000, 2007). As noted both value creation and capture are informed by the underlying assumptions of technological paradigm and what customers want, how they want it and how they can be enticed to pay for it (Teece, 2010). A technology can not address these assumptions on its own unless it uses a specific business model. Thus, the business model of the technology is an organizing framework which shows how a technology can achieve its full potential by creating and capturing value. To conclude, no technology can succeed without a business model and any given successful business model is based on a potent technology.

Constant changes in consumers' demands create new business models and new technologies. These changes take place within existing technological paradigms and progress along technological existing trajectories or create new ones. Many current technological paradigms and trajectories did not exist twenty years ago (e.g. share economy paradigm and technologies behind business model of firms such as air BnB). Drawing on this logic it can be argued that technological paradigms and trajectories are in fact business modelling trajectories and business modeling paradigms. Technologies that address related problems use similar business models that are based on or locked-in an existing dominant paradigm. Radical changes in technological capabilities or shifts in demands cause technologies and their business models to break out from of a dominant paradigm and develop an emerging one (Dolfsma & Leydesdorff, 2009). History of mobile phone technology and success of touch-screen smart phones is a vivid example of this phenomenon. The emergence and success of cloud computing is another manifestation of this phenomenon which creates two particular business modeling

trajectories. To understand this phenomenon, let's first, see what cloud computing technology is.

WHAT IS CLOUD COMPUTING?

The United States' National Institute of Standards and Technology (NIST) defines cloud computing as "....a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction." (Mell & Grance, 2011). It is also called 'on-demand computing', 'software as a service' (SaaS), or the 'Internet as platform' (Hayes, 2008). Regardless of its name, cloud computing as a technology subscribes to a new paradigm because it addresses computing problems differently. In a more technical term, the Cloud Computing paradigm creates a new approach to combine computing hardware and software. It involves "both the applications delivered as services over the Internet and the hardware and systems software in the data centers that provide those services" (Armbrust, Stoica, et al., 2010, p. 50). The services are referred to as Software as a Service (SaaS). The data center hardware and software is what is called a Cloud (Armbrust, Stoica, et al., 2010; Marston, Li, Bandyopadhyay, Zhang, & Ghalsasi, 2011b; Zhang, Cheng, & Boutaba, 2010). A Cloud can be made available in a pay-as-you-go manner to the general public which is then called a Public Cloud or be made as internal data centers of a business or other organization, not made available to the general public in the form of Private Cloud (Armbrust, Stoica, et al., 2010). Hence, the concept of cloud in its broadest terms is defined by a shift from locally installed programs to on-demand software which can be made available to various users on demand by being on the cloud. This shift which is fundamentally in the geography of technology is the defining feature of the cloud computing (Hayes, 2008). By virtue of this shift

in the logistics and geography of computing, the cloud computing disrupts the traditional IT paradigm which is essentially an internally developed, monitored and managed process. Consider for example the traditional office package as opposed to the cloud-based Google Docs: "when you create a spreadsheet with the Google Docs service, major components of the software reside on unseen computers, whereabouts unknown, possibly scattered across continents" (Hayes, 2008, p. 9). Thus, cloud computing represents emergence of a new paradigm in the science of providing information technologies.

HOW CLOUD COMPUTING CREATES VALUE

The value creating potential of cloud computing is simple. It opens numerous doors to create new 'use value' by delivering "all the functionality of existing information technology services (and in fact enable new functionalities that are hitherto infeasible) even as it dramatically reduces the upfront costs of computing that deter many organizations from deploying many cutting-edge IT services" (Marston et al., 2011b, p. 176). As such, Marston et al. (2011b, p. 178) argue that cloud computing as a new technology is suitable for:

- Businesses that use compute-intensive analytics,
- Businesses left behind IT revolution in less-developed countries,
- New businesses and expansion of established businesses by providing an almost immediate access to hardware resources, with no upfront capital investments for users, leading to a faster time to market in many businesses,
- Group of organizations with similar businesses because it becomes an adaptive infrastructure that can be shared by different end users, each of whom might use it in very different ways.

- Innovative companies because it lowers IT barriers to innovation,
- Growth-oriented companies by making it easier for businesses to scale their services. Since the computing resources are managed through software, they can be deployed very fast as new requirements arise. In fact, the goal of cloud computing is to scale resources up or down dynamically depending on client load with minimal service provider interaction.
- Developing new computing-intensive applications that were not possible before such as a) mobile interactive applications that are location-environment- and context-aware and that respond in real time to information provided by human users, nonhuman sensors (e.g. humidity and stress sensors within a shipping container) or even from independent information services (e.g. worldwide weather data); b) parallel batch processing, that allows users to take advantage of huge amounts of processing power to analyze terabytes of data for relatively small periods of time; c) business analytics that can use the vast amount of computer resources to understand customers, buying habits, supply chains and so on from voluminous amounts of data; and d) extensions of compute-intensive desktop applications that can offload the data crunching to the cloud leaving only the rendering of the processed data at the front-end, with the availability of network bandwidth reducing the latency involved.

Drawing on Marston et al. it can be argued that cloud computing changes the value creating logic of traditional IT business models in three ways. First, it challenges the prevalent assumptions about the accessibility and availability of IT. By making IT services available and accessible in new ways, perceived limitations in initial costing, investments, setup complications and speed as well as ease of delivery will be removed. Second,

cloud computing opens new horizons on making IT available and accessible in places where it was not possible or feasible before, making IT available to more users from a wider spectrum of demands. Finally, by offering IT on demand it changes the perceived usefulness of IT services as less-flexible and rigid offerings. All in all, cloud computing enables creation of new 'use value' by making IT-based offerings available to new people and new place in a more flexible and timely manner. That said, the next question is how cloud computing can capture new value created in these ways.

HOW VALUE OF CLOUD COMPUTING CAN BE CAPTURED

The value capturing potential of cloud computing lies in its ability to commercialize the dramatic reduction in the cost per unit of computing and the upfront costs of computing that deter businesses from using various IT services (Marston et al., 2011b). Cloud providers entice clients to join the cloud using this promise. They can then convert this revenue into profit because the clouds operate on extremely large-scale, commodity-computer data centers at low-cost location (Armbrust, et al., 2010). As Armbrust et al. (2010) argue, this factors "combined with statistical multiplexing to increase utilization compared to traditional data centers, meant that cloud computing could offer services below the costs of a medium-sized data center and yet still make a good profit" (p. 52). The profit formula is simple. Companies can access customized state-of-the-art computing services on a pay-as-you-go and/or subscription formats.

Let's have a look at three value-capturing scenarios. First, when demand for a service varies with time cloud computing pay by the hour for computing resources would lead to massive cost saving compared to traditional hosting (Armbrust, et al., 2010; Garrison, Wakefield, & Kim, 2015; Marston et al., 2011b). In the second scenario, demand is unknown in advance. In this case, subscribing to the cloud on an on-demand basis would give the

business a capacity to deal with operational complexity and uncertainty more efficiently (Armbrust et al., 2010). Finally, pay by the hour for computing enables analytics-intensive companies to finish computing faster when performing batch analytics. In all these scenarios and many similar ones, the value capturing potential of cloud computing is associated with its pay-as-you-go formula which companies treat as a conventional capital expense to operational expenses (Armbrust, Stoica, et al., 2010; Garrison et al., 2015; Hayes, 2008). All in all, reduced costs per unit of computing enables a more efficient capture of exchange values with higher margins. This would help cloud computing companies to entice more customers to pay for their IT services in an enhanced more flexible in pay-as- you-go and on-demand manner.

CLOUD COMPUTING AND BUSINESS MODELS: TWO TECHNOLOGICAL TRAJECTORIES

The foregoing sessions briefly discussed the value creation and capturing potential of cloud computing. As noted, a business model is a framework that combines these two. Business models make use of cloud computing by benefiting from the synergistic power created by the convergence of two forces. First is the “IT efficiency, whereby the power of modern computers is utilized more efficiently through highly scalable hardware and software resources” (Marston et al., 2011b, p. 177) and the second is the operational agility or strategic resiliency “whereby IT can be used as a competitive tool through rapid deployment, parallel batch processing, use of compute-intensive business analytics and mobile interactive applications that respond in real time to user requirements” (Marston et al., 2011b, p. 177). The notion of ‘business modeling’ is used to demonstrate how cloud computing and business models interact. Business modeling in its broadest meaning refers to the process of creating and constantly adjusting

business models to maintain their evolutionary fitness (Najmaei, 2014a; Najmaei et al., 2015). Understanding the business modeling side of cloud computing is just as important as understanding the technology side itself. Without a proper business modeling, cloud computing fails at fulfilling (i.e. creating use value) its potential and never succeeds at markets (i.e. capturing exchange value). If the cloud computing represents a paradigm shift in IT, then there would be two potential technological trajectories along which business models can be developed. More specifically, business modeling in the context of cloud computing technology takes two forms each representing a technological trajectory. These two are namely the business modeling with cloud computing (BMCC) and the cloud computing business models (CCBM). The next two sections explain these two trajectories.

BUSINESS MODELING WITH CLOUD COMPUTING (BMCC)

First, when cloud computing enables or enhances existing business models which use traditional IT, the process shall be called the business modeling with cloud computing or more simply cloud-computing enabled business modeling. This trajectory is growing rapidly on a worldwide scale as more businesses across industries are adopting the cloud computing and incorporating the cloud technology into their existing business models (Garrison et al., 2015; Marston et al., 2011b; McAfee, 2011; Zhang et al., 2010). Few examples include universities which adopt cloud-based online education systems, banks which use cloud to store and process transactions data, manufacturers which adopt cloud to manage their production across a diverse network of suppliers, retailers which use cloud to more quickly and efficiently manage their inventory and category management.

This trajectory is important because an enhanced speed, availability and efficiency of cloud computing enable existing business models to

become more agile and competitive. The challenge, however, is to transit from a traditional-IT enabled business models to cloud-enabled ones in a smooth and ideally least disruptive way. A study by KPMG in India suggests that privacy, security, cultural and structural resistance, execution risks and complexities and regulatory ambiguity are some of the most important challenges faced by executives when planning to execute this transformation (Parakala, Udhas, & Khanapurkar, 2011). Not every executive is well equipped and suited to lead this transformation: "...the true benefits of cloud computing will surprise you. But you'll need the right people to lead the transformation" (McAfee, 2011, p. 124). Although it is not an easy task and in many cases it has to be outsourced to cloud experts but given the current trend (Chang et al., 2010; Hashem et al., 2015; Marston, Li, Bandyopadhyay, Zhang, & Ghalsasi, 2011a; Prasanth, Bajpei, Shrivastava, & Mishra, 2015; Qian, Luo, Du, & Guo, 2009; Ranjan, Buyya, Nepal, & Georgakopoulos, 2015; Weinhardt et al., 2009; Zhang et al., 2010) it seems reasonable to argue that future belongs to cloud-enabled business models. Therefore, business modeling with cloud computing seems to be a worthy strategic direction to take. McAfee (2011) in support of this trend states: over time the economics of building and running a technology infrastructure will favour the cloud over on-premise computing" (p.131). Furthermore, business modeling with cloud computing not only permits many companies to concentrate on their core competencies while leaving the task of running IT infrastructure to the cloud service providers (Parakala et al., 2011) but also to develop new innovative competencies to target more customers in new markets. Through the development of virtual and "open" business processes, cloud computing enables its various stakeholders including customers, business partners, suppliers, etc. to connect and do new businesses more seamlessly (Parakala et al., 2011).

THE CLOUD COMPUTING BUSINESS MODEL (CCBM)

C

The first business modeling trajectory within the paradigm of cloud computing technology was about different ways that cloud computing could improve functionality of existing businesses and transform performativity of their business models. As interesting and potentially transformative as it sounds, this trajectory is only one side of the story. A look at the cluster of technologies formed around the cloud computing shows another trajectory that is just as potential to transform economies as the first one. This trajectory is not about cloud-enabled business modeling or transformation of other business models by adopting the cloud computing but is about formation of cloud-based business models. That is, developing business models that are entirely based on the cloud computing. These business models can be called 'cloud computing business models'. Some examples of such business models are Drop Box and Google Docs. They are independent entities whose existence depends entirely on the cloud computing. They did not exist before the invention of cloud computing. They create value by helping millions of people in both public and private sectors share, store and transfer files using the cloud technology. They also capture this value using various pay-as-you-go and subscription plans. In addition, some of the world's pioneering IT firms have begun to develop separate divisions, entities and spin-off companies with their own business models to tap into this market. Examples of such business models are the Google App Engine TM, AMAZON Web Service TM, and Microsoft Azure TM.

These business models are used by autonomous and independent entities which offer computing services over the internet to clients and have the ability to be joined to other related technologies including Grid Computing, Utility Computing, virtualization and Automatic Computing (Zhang et al., 2010).

The cloud computing business models are service-driven and can generally be grouped into

Figure 1. BMCC vs. CCBM

three different service business models which deliver Infrastructure as a Service (IaaS), Platform as a Service (PaaS), or Software as a Service (SaaS) (Zhang et al., 2010). These business models can be made available solely to the general public in the form of public clouds or to clients in the private sector in the form of private clouds to be used exclusively by a single organization or even in a hybrid form to both the general public and the private sector (Armbrust, Fox, et al., 2010; Prasanth et al., 2015; Zhang et al., 2010).

It is to be noted that, developing business models for cloud computing is different from but closely related to the process of business modeling with cloud computing. More specifically, the two trajectories converge on a technological path through which the cloud computing business models allow firms to do their business modeling with the help of cloud computing. The technological cluster shaping around these two trajectories enables this emerging paradigm to delineate its boundaries more clearly as a revolutionary rather than an evolutionary change in the IT paradigm which transforms both the provision of IT services (CCBM) and the way such services are adopted and used by organizations in both public and private sector (BMCC). The discussion outlined here has important implications for theory, practice and research which will be illustrated in the next section.

IMPLICATIONS AND FUTURE RESEARCH DIRECTIONS

Discussions of the link between the cloud computing technology and business models of companies which offer and/or adopt cloud computing are missing in the literature mainly because the boundaries between these two issues are somehow unclear. The primary contribution of this paper is to address this gap. It was argued that in the wake of cloud computing era the business landscape is changing by two business modeling forces: first the existing business models are transformed by the cloud computing. The cloud technology is making them more agile, adaptive and competitive. This trend is progressing along a technological trajectory which can be called business modeling with cloud computing (BMCC). Second, new business models are developed entirely based on the cloud computing breeding new entities and forming new industries and technological clusters. This trend is, however, progressing along a different trajectory which can be called the emergence of cloud computing business models. Figure 1 schematically illustrates this conceptualization.

Porter and Millar (1985) argue that IT changes business landscape in two interrelated ways: either by revolutionizing the established ways of doing business or by creating entirely new ways to do business. The two business modelling trajectories

within the cloud computing paradigm conform to this logic and point to an implication for the theory and practice of business in the era of cloud computing. The adoption of cloud computing seems essential especially in computing-intense industries, so is having a well-functioning business model. The challenge is to make sure that the cloud technology contributes to both value creation and value capturing aspects of the business model. A business model functions well only when its value creation and value capturing parts are well-aligned. Cloud computing enhances both creation and capture of value. The main challenge is to develop the internal alignment between these two (Low, Chen, & Wu, 2011; McAfee, 2011). This alignment is likely to disrupt the business modeling routines of a business but will pay off if properly planned and done under expert supervision. Note that, business modeling with cloud computing is path-dependent whereas the cloud computing business models are path creating. These two interact within the paradigm of cloud computing. Therefore, managers should keep abreast of cloud computing business models to successfully develop strategic scenarios when planning their business modeling with the cloud.

CONCLUSION

On a final thought, any new phenomenon is a fruitful field of research. Numerous unanswered questions exist with regard to the interplay between business models and cloud computing. First, little is known about how exactly small and large companies differ in their capacity to adopt cloud computing technologies. Similarly, little is known about how existing business models are transformed into cloud-enabled ones and how service companies differ from manufacturing ones in performing this process. Secondly, cloud computing business models have primary been developed secretly by large IT companies such as Microsoft and Amazon. Little investigation has been conducted to describe how these business

models have been planned, designed, executed and being managed. Addressing these questions requires exploratory, context-specific case studies which can enable rigorous theory-building and cumulative knowledge creation in both trajectories. This chapter is only a first step in this direction and should be regarded as a starting point for a lively debate on the theory and practice of business modeling in the context of cloud computing.

KEY TERMS AND DEFINITIONS

Business Model: The strategic logic that defines how a technology creates value and how its value can be captured.

Business Modeling: The process of continuously managing business models.

Business Modelling with Cloud Computing (BMCC): A business modeling process in which existing business models adopt cloud computing to improve their agility and functionality.

Cloud Computing Business Models (CCBM): A business modeling process in which new business models based entirely on the cloud computing (its value creation and capture potential) come into existence.

Cloud Computing: A new technological paradigm in IT that is based on computing services as utility and provides them on a pay-as-you-go basis to public and private sector businesses.

Technological Paradigms: A model or pattern of solution of selected technological problems.

Technological Trajectories: The pattern of normal problem solving activity on the ground of a technological paradigm.

Value Capture: The act of capturing profit from a technology by developing a profit formula that entices customers to pay the specified price to obtain the technology and converts the revenue into profit.

Value Creation: The act of creating a value proposition for a technology that clearly defines its benefits/value for customers and specifies how they can be perceived as useful and unique in the market place.

Understanding Cloud Computing in a Higher Education Context

Lucy Self

University of Sussex, UK

Petros Chamakiotis

University of Sussex, UK

INTRODUCTION

This chapter explores cloud computing (CC)—an internet-based type of computing which allows users to share resources which are provided to computers or other remote devices (Hasan, 2011)—within a higher education (HE) context. The study is premised on the view that university students increasingly rely on online resources, electronic media and computing applications for nearly all their work, which has been seen as improving the quality of university studies (e.g. Robinson & Schlegl, 2005). Given the limited number of studies in this area—reviewed in the next section—this chapter aims to advance understanding of CC in HE by adopting an innovative methodological approach involving suppliers, implementers, and end users of CC in a selected HE context. The study—which is qualitative and exploratory, and draws on interview data—informs the extant literature and offers recommendations for researchers, practitioners, and universities. In what follows, the authors discuss the extant literature and then move on to present the research study.

BACKGROUND

CC is a relatively new phenomenon in the technology industry, developed from traditional hosting, which is becoming pervasive in numerous sectors (Armbrust, 2010). Mell and Grance (2011) consider it “a model for enabling ubiquitous,

convenient, on-demand network access to a shared pool of configurable computing resources that can be rapidly provisioned and released with minimal management effort or service provider interaction” (p.2). It is not clear when the term CC was officially coined, because it has been used for many years in network diagrams to depict an area of uncertainty (Stevenson, 2009). It is believed the term was coined in 2006 when large companies such as Google and Amazon Web Services started naming their hosting services as CC (Regalado, 2011). CC has been viewed as a disruptive technology; as Krikos (2011) puts it, “*CC has all the markings of a disruptive technology—those that change the game as it’s currently played both by traditional software licensing companies and by private, on-premises datacenters*” (p.2). A disruptive technology often begins by only satisfying a niche segment of the market—for example CC being best suited to businesses ‘*born on CC*’—and later expanding to other sectors (Danneels, 2004).

From a technical perspective, the extant CC literature posits different CC service models:

- **Infrastructure as a Service (IaaS):** When the customer is able to provision processing, storage, networks, and other fundamental computing resources.
- **Software as a Service (SaaS):** Which allows the consumer to access the provider’s applications running on a **cloud solutions (CS)** but cannot manage the underlying infrastructure.

- **Platform as a Service (PaaS):** Where the customer can control the applications but not the infrastructure (e.g. Mell and Grance, 2011).

Further, CC types may also vary; from ‘*Private Cloud*’ (a high cost option but also the most secure, often preferred by banks and governments), through to ‘*Community*’ (shared by multiple organizations), ‘*Public*’ (allowing pay-per-use) and finally ‘*Hybrid*’ (a mix of the previous) (Chou, 2015).

However, this chapter is interested in CC in the HE sector in particular. Within this context, Sultan (2010) discusses the reasons that it adds value for universities: Firstly, the rapid amount of change in the technology industry puts a lot of pressure on universities to keep up with the ever changing software and hardware; this is not always easy for institutions as they are often under governmental pressure to reduce spending. Therefore, investing in CC prevents universities from having to purchase hardware, which is costly (Wheeler & Waggener, 2009). In turn, it also means that universities can reduce labor costs relative to the management of information technology (IT) systems. Moreover, it is difficult for universities to develop their own premise infrastructure to achieve the economies of scale that a CC provider can achieve, which also leads to cost savings (Katzan, 2010). By allowing a CC provider to maintain the infrastructure, the pressure is also taken off the IT staff at the institution (Ercan, 2010). Further, moving staff away from the low skill tasks can potentially allow them to be reallocated to more value adding activities (Low, Chen & Wu, 2011). Another important feature that CC can bring to universities is collaboration, by, for example, the sharing of resources, such as lecturers, learning content, and amongst students too. This could happen not just internally, but with other universities as well (Wheeler & Waggener, 2009).

In the UK, universities have begun to take CC seriously. For example, London South Bank University (2014, May 6) have recently adopted

CS, confirming a deal for £14 million for IBM’s Exceptional Student Experience. This has numerous benefits: it (a) incorporates analytics, mobile, social and IT security; (b) allows students to access university applications from mobile devices, and use social communities for file sharing; (c) encourages more interaction between students; and (d) gives access for teachers to assess and feedback online (Miller, 2008; Rao, Sasidhar & Kumar, 2012; Sasikala, 2011).

Katz (2008) sees CC in HE as more of a necessity. As he puts it, “*students will arrive on campus with their own IT architectures and service arrangements. These students... will have little use for or patience with college or university offerings that underperform or force them to lose precious connections to people and processes that they have accumulated since childhood*” (p.18). Therefore, whereas Sultan (2010) believes moving to CC is more of a logical step for universities, Katz (2008) argues they will have to out of necessity. Building on this view, Alabbadi (2011) proposes that universities should carefully assess budgets and challenges to choose CC infrastructure which is best suited to their current IT activities.

Recently, however, it has been argued that CC in the HE context does not come without challenges. For example, Culley and Panteli (2015) found that IT staff at universities may view CS as a threat for their jobs; thus, a repositioning of IT services in the HE sector might be necessary. As they put it,

[HE IT staff should] develop a new suit of capabilities, so that the IT department can function when most of the technology is delivered by the cloud [...] IT staff can act as the bridge understanding the business and the technology. (p.60)

Clearly, as it follows, CC is a new, prevalent and disruptive technology with unprecedented benefits for both universities and students and yet there is a clear lack of empirical evidence to enable understanding of CC within the HE context, since much of the extant literature is based around

the pre-implementation phase of CC in HE. Also, this literature is limited in, for example, the impact of CS on HE IT departments (Culley & Panteli, 2015). What about how this is experienced by others—e.g. developers and users—involved in CC in HE? What about its overall impact on HE? In this study, the authors take a more holistic approach by adopting a multi-perspective research approach and considering the perceptions of different types of individuals involved in CC within the HE context, which is described next.

THE RESEARCH STUDY

Methodological Approach

The study is qualitative due to the newness of this topic and involves a multi-perspective approach in terms of data collection in order to gain deep understanding of the phenomenon under investigation. Semi-structured interviews were conducted in February/March 2016 with three groups of participants:

1. **CS Suppliers:** Four employees of a global, Fortune-100 technology company, Epsilon (a pseudonym).
2. **CS Implementers:** Four employees of a UK university's IT department (Hudson University; a pseudonym).
3. **CS End Users:** Four students at Hudson University.

This multi-perspective approach is robust in that it offers the perceptions of both users and developers as well as other individuals involved in the implementation of CS within the HE context. A total of 12 in-depth, semi-structured interviews were conducted, involving open-ended questions which allowed for the participants' experiences and stories to emerge. The interviews lasted for about 40-50 minutes each and the interview data were analyzed following a manual, qualitative thematic analysis approach (Braun & Clarke, 2006).

Analysis was interpretive and inductive—guided largely by the participants' perceptions—and allowing for themes to emerge purely from the data, in line with the exploratory character of the study. In presenting the findings, the names of the participants as well as those of the selected organization (i.e. Epsilon) and university (i.e. Hudson) were anonymized using pseudonyms.

Research Findings

Presented first in this section are the research participants along with their main demo-biographical characteristics (Table 1).

Presented next as three stories are the findings from the qualitative analysis for each group.

Epsilon Staff

There was consensus among Epsilon participants that,

[CC] is the ability to have an underlying IT environment that supports innovation by providing flexibility, speed and agility to allow that innovation to meet the changing requirements of a client core business... (Bert)

Interestingly, Epsilon participants argued that CC constitutes a hidden technological force which serves as an enabler of efficient work that HE students largely benefit from; yet it remains unacknowledged:

I think [students] indirectly benefit from CS. CC is the enabler that gives [students] the agility, speed and flexibility, so something else that provides them benefit. Quite often what students don't realize, they think 'this is a fantastic mobile application or website,' what they don't think is, 'wow, I love the CC that this sits on.' (Bert)

Its disruptive character and potential value was also highlighted:

Table 1. Presentation of the research participants

	Pseudonym	Gender	Age Group	Tenure (in Years)	Subject of Studies	Area of Work*	Organizational Role
Epsilon Staff	Alex	Male	16-25	4	Business and Management	Professional Services	Cloud Technical Sales
	Bert	Male	36-45	18	Economics and Politics	IT Services	Head of Business Development of Cloud Division
	Charles	Male	46-55	5	Marketing	IT Services	Cloud Business Development Executive
	Derek	Male	46-55	30	Chemistry and Economics	Marketing, Sales and IT	Academic Initiative Leader for Europe
Hudson University IT Staff	Edward	Male	26-35	15	Psychology	Infrastructure Services	Head of Platform Development
	Fred	Male	36-45	15	Medieval Studies	Client Services	Senior Information Delivery Manager
	Graham	Male	36-45	20	General IT Training	Client Services	Software & Technical Support Officer
	Harry	Male	46-55	25	Engineering	Infrastructure Services	Head of Technology & Architecture
Hudson University Students	Ian	Male	16-25	4	Computer Science with Management	IT at a Cosmetics Company	HE Student
	Jack	Male	16-25	4	Business and Management	Technology Company	HE Student
	Karl	Male	16-25	4	Computer Science	Technology Company	HE Student
	Lewis	Male	16-25	4	Physics	N/A	HE Student

* For University of Hudson students, this section refers to the type of company within which they carried out their placement year (internship).

Having an alternative and compelling value proposition that competes with those sort of disruptive issues is important [for universities]. (Charles)

The participants here posited a shift in terms of the activities that will hereafter be undertaken by university IT departments:

IT staff [at universities] will spend less time managing PCs and physically locking stuff down. They will be spending more time on the network that enables people to have flexible access and they'll be spending more time on security. (Derek)

This led to the idea of physicality and the benefits afforded by CS in HE contexts. For example,

Every square foot they had would be better served serving their core business rather than housing a computing environment. (Bert)

The issue of security was also found to be related to the above:

A lot of universities have a lot of physical security, and that is fine apart from the fact that, as history has already proved to us, if people either can get past the physical security or your security risk is already inside your network – you've only got to look at people like Edward Snowden. (Derek)

The above quote that rather than have IT staff keep the datacenters secure, universities with CC could utilize those staff members more efficiently.

This way, CS could contribute to taking the focus of universities away from managing datacenters and putting it back on delivering education.

Moreover, Epsilon participants shared their views about the future impact of CS on HE. On the one hand, Charles argued that there is an expectation that more tailored and industry-specific CS will start being developed, for example bundled services aimed specifically at universities. Overall, the participants used the hotel industry and the case of Airbnb, Inc. in particular to stress the level of impact CC can have on a business model. The question that was raised was: Why would a university ‘own’ its students since CC can enable access to foreign universities and remove the issue of tuition?

In expressing his views about the future impact of CC on HE, Bert outlined two reasons:

One is the immediate value, speed and agility it brings and secondly the future of IT is served not just by the benefits that Cloud can bring today but the way in which Cloud will position data to drive cognitive analytics on top of it. The idea of universities using cognitive analytics in the future for better management could be used for things such as tracking students who are performing poorly or helping to pick modules for students based on their preferences.

Finally, Alex suggested the up and coming nature of CS in HE:

I think it's a snowball effect, once you see a number of universities leveraging Cloud services, you'll see the technology within universities increase even more.

Hudson University IT Staff

This group agreed that CC solutions enhance HE:

I think it is enhanced because there are things that you can do because of the scale of some CC

which would never feasibly be possible if you only ever have internal IT. (Harry)

The issue of resistance was posited among Hudson IT staff:

It's very difficult for an IT department who is used to having everything in its own sphere of control to have it outside of its sphere of control, even if that sphere of control is statistically likely to provide a higher up time than we do. (Edward)

However, IT Staff thought that moving workloads to the CC would not lead to redundancies; rather, it would encourage staff to retrain to become more useful in value adding areas:

Our plan was not to make anyone redundant but it's actually to redeploy them to more valuable work, moving up the value chain and getting people doing interesting valuable work because there's clearly value to complex projects. (Edward)

It was mentioned that these cultural fears of CC came from the early 2000s when there was a large shake up in technology jobs due to outsourcing.

Data protection and IT security seemed to be a concern. As a university, issues of intellectual property (IP) need to be kept very secure; however, the university is taking a risk-based model around CC as the benefits lost without CC would be too great for the university:

People in all areas have concerns about security, particularly in light of TalkTalk—there will always be, to an extent, the argument of we've done it ourselves for years and it's all been fine, how do we know it's still going to be fine if we move it to a Cloud service? (Harry)

The ability to supply teaching virtually in order to reduce the congestion on campus was found to be critical. With the increasing number of students, it's no longer becoming a viable option to purely work on an on-premise basis, therefore moving

to a CS are becoming more of a necessity rather than just a benefit; and this may lead to a potential change in the way in which teaching is delivered:

We need a certain number of students to be the kind of university that we have the aspiration to be and that means challenges for capacity on campus. It's expensive to invest in infrastructure but if we can mitigate that through delivering some classes remotely and reducing the need to be on campus then we're clearly in a good position [...] we need to think of new hybrid teaching models where some of the course content is delivered on-line or is delivered through webinars and virtual classroom learning. (Edward)

In terms of how CC businesses could target universities better, this came down to cost and licensing:

We are massively price aware, we aren't just choosing based on return-on-investment (ROI) we're choosing on opportunity cost on spend because we're constrained to the point if a product would give us a positive ROI, we might not be able to go ahead with it if there's something else we could put in if it'll give us more value. (Edward)

However—similarly to participants from Epsilon—Hudson IT staff commented on CC sustainability:

We have reached a sustainable model in which the university is continuing to invest which means [CC] is becoming more mature, more accessible and more usable and therefore of greater value to us as end users. (Harry)

Overall, it was found that adding value was more important than price; therefore, Hudson IT staff argued that bundling products together, e.g. Microsoft bundling Office licenses into their CC offering, could be of significant value.

Hudson University Students

When asked to define CS, students emphasized the possibilities for mobile work as well as for synchronous collaborative work that these afford:

Cloud to me is being able to be mobile whilst working. If I save a document to the Cloud it means that other people that have access to that Cloud can access it anywhere around the country and even globally. (Jack)

CC was found to make collaboration between students, and also between students and lecturers significantly easier:

It's easy off the Google Docs and you can email it off to the lecturer or they can review it and it allows the lecturer to then look on the file and add comments and review it. (Karl)

Further to the issue of collaboration, the opportunities for knowledge sharing that CC was seen as enhancing were thought of by the students as paramount. Students highlighted the inter-university aspect of this, arguing that CS may allow them to access materials from top universities at a global level, thus improving their learning experience significantly:

We already have [...] something called the '[Omega, a pseudonym] Physics Network' and they have a room that has cameras dotted all around it, a big projector and then there's ten or so in the [area of the UK] that can share lectures. (Lewis)

I definitely think it would. I would be able to use lectures from the best universities in the US and the best lecturers in Oxford and it would just be my normal course. (Graham)

DISCUSSION AND RECOMMENDATIONS

This section discusses (a) the themes that emerged from the study and their contribution to the extant literature; and (b) recommendations for cloud suppliers, universities and students. It has to be noted that interviewees spoke about different CC service models; for example, Epsilon staff shared their views from an IaaS perspective, whereas Hudson IT staff and students from SaaS and PaaS perspectives. Further, though all themes add equally to the literature, Figure 1 below shows the relationships between the different themes, i.e. the degree to which the different groups agree on certain themes.

Emergent Themes

A dominant theme amongst the participants from Epsilon and Hudson IT staff was the idea of CC as a sustainable competitive advantage and its potential for value creation for organizations. It was purported that the more mature CC becomes,

the more value it adds to HE institutions. This expands the traditional literature on competitive advantage sustainability and cost reduction or differentiation as a driver of innovation (Porter, 1985), by explaining how CC can contribute to the development of a competitive advantage in HE. With a more granular look, CC capabilities in HE relate to the notion of temporary advantage (D'Aveni, Dagnino & Smith, 2010) suggesting that the volatility of today's markets only allows products to have an advantage for a limited time before another innovation emerges (Christensen, 1997).

Epsilon participants and Hudson IT staff both spoke about the fears around CC. These fears stem from cultures developed inside IT departments that believe outsourcing internal IT infrastructure to an external supplier would lead to jobs being lost. Some believed it was linked to the early 2000s when businesses saw a big shift to outsource their infrastructure. However, both groups stressed that this could be seen as an opportunity for current staff to develop different skills, corroborating and adding to recent literature speaking about employee

Figure 1. Relationships between the emergent themes from the three groups

resistance and also potential repositioning and new capabilities of universities' IT departments (Culley & Panteli, 2015; Low et al., 2011).

Security featured as another fear, especially after recent data leaks from big companies such as TalkTalk. The study stresses the added importance of this within the HE context due to IP issues characterizing universities' research activities. However, Epsilon and Hudson IT staff participants agreed that the benefits that HE institutions could obtain from a CS were greater than the limited chance of being hacked. IT staff also agreed that if someone really wanted to access their data, it would not be incredibly difficult for them to hack their on-premise infrastructure, thus taking a risk-based model towards CC is necessary. CC security is an area heavily covered in the literature, however, universities taking a risk-based model towards CC is not.

All three groups agreed that CC is a hidden force that will enhance education. Epsilon participants believed that this is down to the capabilities of CC which will allow higher levels of collaboration and will act as a base for cognitive analytics. IT staff claimed it would enhance education because it will allow greater scale than they could provide on-premise and students stressed they would benefit from it as it could potentially allow them to receive lectures over the internet from top institutions.

An idea put forward by Epsilon participants was that CC will completely alter the current model of HE Institutions by enabling new types of universities to set up online with much faster processes and cost far less for students. Or, similar to the cases of Airbnb, Inc. and Uber, lectures could be delivered virtually and tutors could be available locally. This may allow students to access the top lecturers globally without having to leave home. This is something that the IT staff agreed with and they added that if the university did not move quicker to tackle this pace of technology, they could seriously lose out. Students thought the idea of having access to top lecturers and cheaper tuition fees would be highly valuable. An

important issue suggested around this by Epsilon was that the universities that do not disrupt the current state now, will only be disrupted later.

An issue that follows from the aforementioned themes is the disruptive aspect of CC as a technological innovation (e.g. Krikos, 2011). These findings challenge deterministic approaches which see technology as a support activity within organizations, and instead highlight its potential to transform existing business models and bring value to organizations, as it is the case with CC in the HE context, which has been shown in the study presented here. Further to its theoretical significance, the study has recommendations for practitioners, which are outlined next.

Recommendations for Practitioners

Universities appreciate value creation and the simplicity of bundling multiple products and services into one license. It is important therefore for CS suppliers to consider this in order to ensure that the value added by their proposed CS has the potential to create sustainable value. If the current model for universities is disrupted by CS, the external suppliers will need to have a part in this process. Therefore, targeting universities effectively should take into consideration the educational boundaries that are being pushed. Further, a significant selling point that CC suppliers could consider relates to another concept mentioned by Epsilon with the idea of an '*Industry Cloud*'; a could offering based off of the needs of specific sectors, for example the HE sector.

It would overall be recommended that universities embrace CC for their own and their students' benefit. It is vital that any cultural perceptions within their IT departments be reassured in an effort to minimize uncertainty among IT staff. A repositioning of universities' IT departments and development of new capabilities for IT staff might prove fruitful. An acknowledgement that today's HE institution business model may be altered due to disruptive technology might also help. Willingness to accept this now will lead

to less disruption in the future; universities that do not technologically progress now might be disrupted by the universities that are willing to take a technical risk. It is finally recommended that university students embrace the opportunities afforded by CC by capitalizing on collaboration as well as accessing materials that exceed the boundaries of the traditional university.

FUTURE RESEARCH DIRECTIONS

The study presented here has limitations which give rise to directions for future research. First are methodological issues, for example, the issue of gender imbalance and limited statistical generalizability due to the relatively small sample. These can be overcome with larger studies and quantitative approaches as well as studies in other sectors, as CC is prevalent in numerous areas further to HE. From a theoretical perspective, researchers could build on the findings reported here to further explore the disruptive aspect of CC and its potential for the creation of a sustainable competitive advantage. Researchers could consider the relevance of the 'Business Model Canvas' (Osterwalder and Pigneur, 2010) examining such issues as value propositions, cost structures, and customer segments.

CONCLUSION

Overall, the exploratory study presented in this chapter was premised on the view that very little is known about CC in HE, despite its popularity and importance in this context. The study shed light on this issue by unpacking themes relating to CC in HE by considering the views of different groups of individuals (suppliers, implementers, end users). These themes add to our understanding in this area and—as discussed in the earlier sections—could be used to guide both future researchers, as well as practitioners in the field.

KEY TERMS AND DEFINITIONS

C

Cloud Computing: A model enabling, convenient, on-demand network access to a shared pool of computing resources.

Cloud Solutions: The delivery of IT services, retrieved through Internet-based tools and applications rather than via a direct server connection.

Data Protection: Legal control over access to, and use of, data in computers.

Datacenter: A group of networked computer servers used for remote storage, processing, or distribution of large amounts of data.

Higher Education (HE): Tertiary education at a university leading to a recognized degree.

Information Technology (IT): The application of computers to store, retrieve, transmit and manipulate data.

IT Security: Protecting information from theft or damage, either via hardware or software and the information stored on them.

License: Agreement that stipulates the terms of use for an application and defines the rights of the software producer and of the end-user.

Virtually: Not physically existing, but made by software to appear to do so.

Vertical Integration Between Providers With Possible Cloud Migration

Aleksandra Kostic-Ljubisavljevic

University of Belgrade, Serbia

Branka Mikavica

University of Belgrade, Serbia

INTRODUCTION

The continuous growth of Internet traffic is significantly pushed by emerging high bandwidth demanding contents. All participants in content provisioning process including content providers, service providers, Content Delivery Networks (CDN) and customers are influenced by bandwidth requirements. Appropriate bandwidth demand estimation and consequently, network dimensioning are of great importance for addressing resource investment. However, peak bandwidth demand varies during the day. Provisioning of self-owned resources that satisfy peak bandwidth demand leads to network underutilization in the periods of low or normal traffic load. Hence, over-provisioning is cost ineffective. On the other hand, under-provisioning of network resources leads to rejection of customers' requests for service provisioning. Considering all aforementioned, vertically integrated providers in content provisioning process need to consider cloud migration in order to minimize costs and improve Quality of Service (QoS) and hence Quality of Experience (QoE) of their customers. Cloud providers maintain large-scale data centres to offer storage and computational resources in the form of Virtual Machines instances at a relatively low cost. Depending on the characteristics, cloud instances are available at different prices. In general, cloud providers offer three different pricing plans, such as reservation, on-demand and spot pricing. With the aim of obtaining

optimal integration charging strategy, concepts like Revenue Sharing, Cost Sharing, Wholesale Price etc. are applied frequently. Involvement of cloud providers into content provisioning process introduces additional complexity for choosing appropriate interconnection contract. The vertically integrated content provider's incentives for cloud migration can induce significant changes in integration contracts, and consequently in costs and requests' rejection rate.

In this chapter different methods of vertical integration charging among providers are analyzed and compared. With the aim of QoS and QoE improvement, providers can perform cloud migration. In that manner, cloud resources utilization concepts like reservation, on demand, and potential application of spot-pricing are going to be analyzed.

BACKGROUND

In order to provide content to the customers, vertical integration between providers is necessary. Term vertical integration refers to interconnection, i.e. physical and logical connecting, among providers operating at different network's levels. For instance, long-distance operator and local operator can be vertically integrated. Intrinsically, interconnection enables customers connected to one network to communicate with customers of the same or different network. It is a set of legal rules, technical and operational arrangements

which providers use to connect their equipment, networks and services. Vertical integration is economical, efficient and it enables achievement of economies of scale (Dai & Tang, 2009). Often applied contracts are Revenue Sharing, Cost Sharing and Wholesale Price. Instead of explicitly defined interconnection tariffs, operators often apply Revenue Sharing, which establishes fixed revenue share among providers. This type of contract is characterized with operational simplicity, and it can rebalance providers' returns when retail prices are distorted for any reason. Some of the greatest challenges that providers are dealing with are increasing profitability of the offered services, assuring higher charges for improved services and obtaining a fair share of the increased revenues. A fair Revenue Sharing contract based on the weighed proportional fairness criterion is proposed by He & Warland, (2006). They also show that non-cooperative strategies between providers may lead to unfair distribution of profit and may even discourage future upgrades to the network. Modelling of non-cooperative interaction between service providers and content provider as a Stackelberg game is performed by Wu, Kim, Hande, Chiang & Tsang (2011). These authors propose Revenue Sharing contract between service providers that jointly provide network connectivity between content provider and customers. They introduce profit division factor into the contract with the aim of social profit's maximization. Revenue Sharing contract between content provider and two service providers under network neutrality debate is observed by Coucheney, Maille, & Tuffin (2014). In this model, service providers enable direct connectivity to a fixed proportion of the content and compete in terms of price for customers. Relations between service providers are established using Revenue Sharing contract in order to maximize customers' welfare.

Revenue Sharing and Cost Sharing contracts are often formulated using Shapley value (Lee, Jang, Yi & Cho, 2013; Bogomolnaia, Holzman & Moulin, 2010). This mathematical method allocates resources according to contributions

of each party in a fair manner. Application of Shapley value in order to obtain a proper revenue distribution between content and service provider with elastic and inelastic demand is proposed by Ma, Chiu, Lui, Misra & Rubenstein (2008). The following formulations of Cost Sharing contract in backbone networks: volume-device, 95th percentile-device, 95th percentile-customer, customer peak-device, aggregate peak-device and Shapley-device, are analyzed and compared by Gyarmati, Sirivianos, & Laoutaris, (2012). The results show that Shapley-device contract better reflects the costs of the customers and improves fairness compared to other observed contracts. Key characteristic of Cost Sharing contract is enabling a compensation for the costs that provider incurs in carrying traffic generated by other providers.

Under Wholesale Price contract, service provider's payment to content provider for content provisioning depends on the established wholesale unit price and the traffic volume. The process of determining wholesale prices for mobile virtual networks operators and relations among vertically integrated incumbents when downstream entries are present under Wholesale Price contract are described by Song (2010). It appears that wholesale price can be the lower limit of the retail price, and determines the competitiveness of mobile virtual networks operators. Related regulatory issues have also been considered and it emphasizes the fact that regulators should have long-term perspective for the market.

In order to improve content provisioning process and assure satisfactory QoS and QoE, bandwidth demand estimation is essential. Content requires a certain minimal bandwidth which assures that customers' experience in content provisioning is satisfactory. Also, content has assigned content popularity factor, addressing the probability of access to certain content. In bandwidth demand estimation, parameter depicting content popularity is an important parameter and has to be included in network dimensioning process. Contents' differentiation according to its assigned popularity is of great importance for load

balancing, as well (Janaszka, Bursztynowski, & Dzida, 2012). Several observations on the suitable content popularity distribution can be found in the literature: Zipf (Zipf, 1932), Zipf-Mandelbrot (Tang, Fu, Cherkasova, & Vahdat, 2007), stretched exponential (Guo, Tan, Chen, Xiao, & Zhang, 2008), Zipf with exponential cut-off tail (Cha, Kwak, Rodriguez, Ahn, & Moon, 2007), etc.

In general, demand has stochastic characteristics. However, it appears that Internet traffic exhibits similar daily patterns and similar peak values every day. Demand attains the highest value in the evening hours, whereas the lowest demand occurs in the early morning hours. Provisioning capacity that satisfies total bandwidth demand is not economically efficient. Hence, content provider's resources would be idle most of the time. In order to avoid over-provisioning, servers' capacity might be constrained by parameter determining the portion of the peak bandwidth demand. The adequate bandwidth of content provider's resources is from 40% up to 60% of the peak bandwidth demand (Li et al., 2011). Intuitively, the less capacity provisioned, less resources are underutilized. However, this situation leads to greater rejection of customers' requests for content provisioning and hence, it must be taken in consideration. A promising solution for this challenge is cloud migration. Providers' incentives for partial cloud migration are analyzed by Li, Zhong, Liu, Li, & Xu (2011). Generic framework that facilitates cost-effective cloud migration of live streaming applications is provided by Wang, Liu, Chen, & Wang (2016). Cost-minimizing framework for migration of content distribution services into the cloud is presented by Qiu, Li, Wu, Li, & Lau, (2012). Costs for partial cloud migration and providers' profits obtained under different providers' integration contracts are analyzed by Mikavica & Kostic-Ljubisavljevic (2016).

Cloud resources are organized in the form of different types of Virtual Machine instances. Instances are available at different prices, depending on the applied cloud pricing plan. Two cloud

pricing plans that are widely implemented among cloud providers are: on-demand and reservation. On-demand pricing plan considers payment only for utilized resources, charging a fixed rate per billing cycle, usually on hourly basis. Cloud instances are available for indefinite time. However, cloud provider retains the right to terminate cloud instance. Unused time (less than an hour) whether end user or another provider terminated connection, charges as a full hour. If the instance is terminated by cloud provider, particular unused time is free of charge. Reservation cloud pricing plan enables reservation of cloud resources for a certain period of time, usually a year or three years. Beside upfront fee for resource reservation, cloud provider's customer pays discounted hourly resource usage price. Reserved resources are available at any time on request. Cloud pricing plans' classification is presented by Kansal, Singh, Kumar, & Kaushal, (2014). Lately, spot pricing has emerged as promising solution for enhancement of cloud provider's resources utilization and decreasing prices for cloud customers. Even with resources reservation and on-demand instances' utilization, some cloud resources remain in idle state. Thus, cloud provider offer its available resources, namely spot instances, in cloud market at lower price with ability to terminate instances when needed. Spot pricing presents dynamic pricing mechanism based on auctions (Toosi, Vanmechelen, Khodadadi, & Buyya, 2016) and reverse auctions (Roovers, Vanmechelen, & Broeckhove, 2012). Cloud customer creates a bid, representing maximum price willing to pay for specific instance. The access to spot instance is enabled as long as bid exceeds cloud provider's last computed market clearing price. Resource allocation and cloud pricing plans are closely related (Pal & Hui, 2013). Revenue maximization along with optimization of capacity allocation under different cloud pricing plans may be achieved by means of admission control (Toosi, Vanmechelen, Ramamohanarao, & Buyya, 2015).

VERTICAL INTEGRATION BETWEEN PROVIDERS

The comprehensive growth of Internet traffic is caused by emerging high bandwidth demanding contents such as video on demand, High Definition Television (HDTV), real time video, online gaming, file sharing and cloud computing. Participants in content provisioning process include content providers, service providers, Content Delivery Network (CDN) and customers. Generally, these participants may perform different combinations of functionalities depending on whether or to what degree an operator's business model implies vertical integration (BEREC Report BoR (12) 130, 2012).

Content providers' main functionality is content creation and aggregation. In addition, content providers establish their own hosting capabilities or deploy their own network infrastructure. Content providers encompass various players such as: platforms enabling transactions (e.g. Amazon, eBay, etc.), social platforms (e.g. Facebook), search engines (e.g. Google, Bing), live and on-demand radio and video services (e.g. broadcasters), entertainment services (e.g. Youtube, Dailymotion, etc.), application providers (e.g. Skype), video on demand (e.g. Netflix).

Generally, term service provider refers to operators selling broadband access and connectivity to the Internet at the retail level and at the wholesale level through transit and other forms of integration. These providers enable connectivity for different types of customers, whether it is end customer of content provider.

CDNs serve as aggregators of content on behalf of content providers. Their function is delivering content closer to the terminating network. CDN is a system of servers, placed at various locations at the network edges in order to enable efficient access from any customers' location. Customers' requests are redirected to the servers nearest to them. Different services provided by CDNs are targeted at the different types of content, such as video services, game services, software distribu-

tion updates, which content providers distribute. Each type of content has its own characteristics, such as data volume, upstream and/or downstream traffic, peak traffic, for which different CDNs can provide added value.

Term customer refers to both residential and business customers of a broadband access in their function of passively consuming content. Generally, customers form downstream traffic volume in consuming the content provided by the content providers. Overlapping between customers and content providers is possible. Players that predominantly act as customers may, in certain situations, act as content providers and provide content and services or applications, e.g. Youtube videos, Internet blogs, etc. Retail customers are private households whereas business customers may range from small to large business and industry customers.

If partial cloud migration is performed, content provider stores all original contents in self-owned servers and serves major part of the customers' requests for content provisioning. A certain part of the content provider's contents is migrated to the cloud resources provided by cloud provider. Cloud provider is a party which provides cloud services and performs activities necessary to ensure its delivery to the cloud customers as well cloud service maintenance. Term cloud service refers to one or more capabilities (application, infrastructure or platform capabilities type) offered via cloud computing invoked using a defined interface (ITU-T Recommendation Y.3500, 2014). In order to ensure satisfactory QoE, cloud provider delivers contents to the cloud CDN. Subsequently, cloud CDN delivers contents to the service provider using a global network. In the periods of low traffic load, content provider's resources can satisfy overall demand so data transfer through cloud CDN is not significant. However, in the periods of high traffic load, cloud CDN serves meaningful data volume. In order to assure the access to the most popular contents, content provider occupies cloud storage capacity according to appropriate cloud pricing plan. When demand exceeds capacity of the

content provider's resources, customer's request for content provisioning will be accomplished if required content is being stored into the cloud. Otherwise, customer's request for content provisioning is being rejected. Therefore, determination of the portion of the contents' replication on cloud has direct impact on requests' rejection, especially in the periods of high traffic load. In order to minimize risk of content unavailability, it is recommendable that cloud migrations occur in the period of low traffic load, so the content uploading to the cloud would not additionally load the system. Content replication during cloud migration assures that most popular contents are available even in the periods of high traffic load and it lowers number of rejected requests for content provisioning. The least rejection rate attains for the greatest content provider's capacity and the greatest portion of cloud migration.

Each provider aims to obtain the highest profit along with satisfactory QoS and QoE which, in long term, assures customers' loyalty. In general, providers' profits can be obtained by deducting corresponding costs from revenues. Service provider's revenue generated from the customers depends on the retail price and number of customers. Their costs largely depend on the selected integration contract. Prerequisite for selecting optimal vertical integration contract which improves content provisioning process is appropriate bandwidth demand estimation. In the context of partial cloud migration, vertical integration is being established among content and service provider. Relations among content and cloud provider are in accordance with the cloud pricing plans. Which cloud pricing plan will be chosen depends on the costs' prediction, demand, content provider's self-owned capacities and tolerance for requests' rejection rate. Vertical integration contracts that are often applied between providers are Revenue Sharing, Cost Sharing and Wholesale Price. Formulations of previously mentioned contracts used in this chapter are provided by Yoon, Yoo & Choi (2010).

In order to enable their customers the access to certain contents under Revenue Sharing contract, service provider shares its revenue with content provider. Hence, content provider's revenue under Revenue Sharing vertical integration contract depends on the service provider's revenue and on the parameter determining revenue share among them. The parameter depicting revenue share among providers is predefined constant value in the range $(0, 1)$. Greater revenue share assures greater revenue for content provider. The opposite state is valid for service providers.

Similarly to Revenue Sharing contract which defines how revenues of content and service provider are shared, Cost Sharing contract defines how costs in content provisioning process should be shared among providers. Extensive analysis of content and service provider's costs in the content provisioning process will be presented later. The parameter defining cost share is constant value in the range $(0, 1)$. Higher value of this parameter provides greater revenue for content provider. In addition, content provider's revenue under Cost Sharing contract depends also on profit margin which indicates a provider's profitability and takes values in the range $(0, 1)$.

The parameter profit margin coexists in the Wholesale Price contract with the same characteristics as in the Cost Sharing contract, as well. Hence, greater values for profit margin implicates greater content provider's revenue. Considering the fact that the same parameter coexists in Cost Sharing and Wholesale Price contracts, these contracts are easy to compare.

Content and service provider's costs are highly influenced with a selection of proper vertical integration contract. Service provider's costs can be divided into cost for customers' requests provisioning and vertical integration payment to content provider. Number of the customers' requests provisioned through cloud CDN depends on the portion of contents' replication on the cloud. Hence, partial cloud migration introduces additional costs. However, cloud migration has numerous short-term benefits including lower

requests' rejection rate, and long-term benefits which consist of customer's loyalty improvement. Analysis of content provider's costs indicates that enhancement of self-owned resources increases costs, which is primary motivation for cloud migration. The appropriate combination of content provider's self-owned resources and the amount of cloud migration should be selected in accordance with the realized profits depending on integration contracts between content and service provider. Content provider's costs in content provisioning with partial cloud migration can be divided into costs for serving part of requests for content provisioning from self-owned resources and costs for cloud assistance. Cloud instances are being occupied depending on the following factors: estimated future demand, necessary storage capacity for desired portion of the most popular contents on the cloud and offered cloud pricing plans. Hence, content provider's costs for renting cloud resources consist of: cost for reservation, if resource reservation is enabled; costs for resource utilizing, expressed as a fixed rate per billing cycle if on-demand or spot instances are being utilized and costs for data transfer from cloud CDN to the customers. Cost for content provisioning from cloud CDN to service provider's network is based on the transferred data volume.

Content provider's profits under Revenue Sharing vertical integration contract increases with revenue share enhancement. Greater content replication on cloud increase costs. Self-owned capacities enhancement increase costs, as well. Profit margin assures certain amount of content provider's revenue. In addition, cost share has considerable impact on profits. Greater profit margin provides greater profits. Likewise, greater cost share leads to greater profits. However, under Cost Sharing and Wholesale Price contracts, unlike Revenue Sharing, increasing of self-owned resources and content replication to cloud has minor impact on profits (Mikavica & Kostic-Ljubisavljevic, (2016). Considering service provider's profits under different vertical integration contracts and different levels of cloud migration

it is notable that higher values of revenue share, cost share or profit margin decrease profit.

Analyzing requests' rejection rate, costs and occupied resources under providers' vertical integration it is notable that cloud migration is preferable. However, content provider is imposed on additional costs. Considering that less popular contents are not likely to be requested, complete contents' replication on cloud would be cost ineffective. Hence, partial cloud migration which involves storing the most popular contents on the cloud is promising solution. In order to achieve the greatest cost savings, appropriate determination of content popularity and demand estimation is essential. In addition, cloud pricing plans in cloud migration may significantly affect content provider's costs, which in turn, may affect on proper selection of vertical integration contract with service provider. Hence, compromising solution is necessary.

FUTURE RESEARCH DIRECTIONS

Revenue Sharing vertical integration contract has proved to be preferable among Cost Sharing and Wholesale Price contracts, when partial cloud migration is performed (Mikavica & Kostic-Ljubisavljevic, 2016). However, only reservation cloud pricing plan has been observed. Hybrid pricing plan which involves partial resources' reservation and on-demand instances provisioning may decrease costs and reduce requests' for content provisioning rejection, concurrently. The impact of these pricing plans on selection appropriate vertical integration contract is subject of further research. Another promising solution for achieving goals of cloud provider's customers, i.e. providers and customers is spot pricing. However, there are some challenges related to spot pricing, including resources' availability and allocation, complexity for customer's understanding, optimal bidding in auctions etc. Migration to Superclouds allows relocation contents from terminating spot instance into the instance in another availability

zone, or even on another cloud provider. This can enhance content provisioning process performances. In addition to observation of different vertical integration contracts and their comparison, aforementioned issues will be addressed in future.

CONCLUSION

The aim of this chapter is to present complex issue of vertical integration between providers involved in content provisioning process. Undertakings that are concerned include content provider, service provider and cloud provider with corresponding CDN along with partial cloud migration. It has to be observed from different aspects. Primarily, appropriate bandwidth demand estimation is of crucial importance. Main reason for this estimation is to mitigate all disadvantages of under-provisioning or over-provisioning of resources. Requests' for content provisioning rejection rate is another relevant parameter since it significantly affects customers' experience in content provisioning process. Cost allocation and predicted profits are decisive factors in investment for partial cloud migration and selection appropriate vertical integration contract between providers. It appears that partial cloud migration can be cost-effective solution for providing contents with satisfactory QoS and QoE along with costs' minimization for maintenance of self-owned resources. Considering the fact that providers' main business goal is achieving the highest possible profits, selection of proper vertical integration contract is essential. In this chapter, Revenue Sharing, Cost Sharing and Wholesale Price contracts between content and service provider have been analyzed and compared. Introducing cloud provider in content provisioning process increases complexity in vertical integration issues, but it may offer (some) different optimal solutions in that process.

KEY TERMS AND DEFINITIONS

Cloud Migration: Storing a portion of the most popular content provider's contents into the cloud resources with the aim of enabling access to those contents whenever capacity of the self-owned servers is occupied.

Cost Sharing: Integration contract which allocates costs to all undertakings in a fair manner. Cost share among providers is defined in accordance with contribution in total costs of each provider in content provisioning process.

On-Demand: Pricing plan which enables cloud providers' customers to pay only for utilized resources per time unit, usually on the hourly basis. Cloud instances are retained for indefinite time.

Reservation: Cloud providers' customers pay an upfront reservation fee in order to reserve cloud resources for a specific period of time. In return, they receive a significant discount on the hourly resource usage price.

Revenue Sharing: Integration contract which defines modality of revenue shares between providers involved in all forms of provider's integration. It is characterized with operational simplicity and possibility of rebalancing the returns of the providers when retail prices are distorted.

Spot Pricing: An auction-like mechanism where cloud providers' customers submit bids, i.e. maximum price they are willing to pay for specific cloud instance. The access to cloud instances is enabled as long as submitted bid exceeds cloud provider's last computed market clearing price.

Vertical Integration: The term refers to inter-connection between all undertakings involved in content provisioning process, enabling physical and logical connecting with the aim of providing the access to contents.

Wholesale Price: Integration contract among providers based on the determination of the unit wholesale price for a given service. Demand and traffic volume are highly dependent on defined wholesale price.

C

Virtualization as the Enabling Technology of Cloud Computing

Mohamed Fazil Mohamed Firdhous
University of Moratuwa, Sri Lanka

INTRODUCTION

Cloud computing has become the newest computing paradigm that has made a long time dream of making computing a utility a reality (Buyya, Yeo, Venugopal, Broberg, & Brandic, 2009). The initial attempt at providing computing as a utility was attempted by IBM through renting its mainframe computing resources to the Wall Street using remotely connected dumb terminals. Then the idea just died down until it again became popular in the early 2000s as cloud computing. Cloud computing makes it possible to purchase and use computing resources similar to utilities such as electricity, water, gas and telephony. The utility model allows the customers to consume any amount of resources and pay for only the resources that have actually been used. Prior to the arrival cloud computing,

computer systems were generally purchased outright. The systems thus purchased had fixed capacity irrespective of the actual demand. Figure 1 shows the capacity-utilization curve developed by Amazon Web Services depicting the usage of disk storage under cloud computing and traditional computing models (AWS, 2012).

From Figure 1, it can be seen that the traditional computing model shown by the step wise resource allocation is unable to follow the demand pattern. On the other hand, the cloud based resource provisioning closely follows the demand pattern in both short term as well as long term fluctuations. Thus cloud computing provides the right solution for any venture irrespective of their nature of business. On cloud computing, the committed computing resources and the money spent would have a very close and strong relationship with that

Figure 1. Capacity-utilization curve
 Source: AWS, 2012

DOI: 10.4018/978-1-5225-2255-3.ch101

of the real demand. This would make the money spent on these resources fully worth. Also cloud computing effectively transforms the money spent on the computing resources into an operational expenditure rather than a capital expenditure that has traditionally been. This helps businesses to utilize their capital fully on core business activities (Jaatmaa, 2010).

BACKGROUND

The technology that works behind to make cloud computing possible is hardware virtualization (Siddhisena, Warusawithana, & Mendis, 2011). In cloud computing, a single system is partitioned and hosted in parallel. These parallel systems can be spawned on demand and allocated to different users (Siddhisena et al., 2011). Once a user has completed his work, the virtual system can be removed and all the resources are released so that they can be allocated to another user in the future.

The virtualized computing infrastructure is created by installing a Virtual Machine Manager (VMM) on the physical hardware (Li, Yang, Kandula, & Zhang, 2010). The VMM provides the necessary isolation and security between the multiple virtual machines running in parallel on a single physical computer. Hosting individual fully functional systems on virtual machines maximizes the utilization of the physical systems as the physical system can be allocated to many customers. When many virtual machines are hosted on a single system simultaneously, its performance may start to degrade after a point due to the competition for resources between the hosted systems. So, in order to maintain the service quality, the maximum number of virtual machines hosted on a system must be limited.

Advantages and Disadvantages of Virtualization

Virtualization of computer hardware results in many benefits along with certain shortcomings.

Though there are a few disadvantages, the advantages for sure outweigh those disadvantages. Ameen and Hamo (2013) have carried out an extensive analysis on the advantages and disadvantages of hardware virtualization.

The most prominent advantages and disadvantages of hardware virtualization are listed below:

- Ability to have better server and application consolidation
- Improve security through sandboxing
- Multiple simultaneous execution environments
- Better use of existing hardware
- Reduction in IT infrastructure costs
- Reduced downtime or increased uptime and faster failure recovery
- Simplified system administration
- Ability to have gradual capacity expansion
- Support for legacy systems and applications
- Simplified system installation and deployment
- Better system and application testing business continuity and disaster recovery capabilities
- Improved business agility
- Better resource sharing and utilization
- Increased flexibility, availability and scalability
- Enhanced security, isolation and hardware independence
- Better load balancing
- Opportunity for single points of failure
- Reduced performance, if not managed properly
- Complicated management interface
- Increased networking complexity and debugging time

HISTORY OF VIRTUALIZATION TECHNOLOGY

The initial work on creating virtualized systems started way back in the early 1960s by organiza-

tions like General Electric, Bell Labs, IBM and MIT (Ali & Meghanathan, 2011). IBM was the first to bring the concept of Virtual Machines to the commercial environment. Virtual Machines as they were initially implemented on IBM's Mainframes are still in use today, though the use of mainframes has diminished with the development of distributed computing along with the capability of low end computer systems. On the lower end of the computing spectrum, namely the personal computer systems, the implementation of virtual systems started only in the 1990s. The virtualization support for the x86 class microprocessors were initially achieved through complex software implementations as the hardware support for such implementations were not available at time (Bugnion, Devine, Rosenblum, Sugerma, & Wang, 2012).

VMware Workstation was the first virtualization solution implemented for the 32 bit x86 based platforms. The virtualization solution implemented for the x86 platform was very complicated compared to that of the mainframe counterparts. The main reason behind the success of the mainframe virtualization was the monolithic single vendor implementation of different components of the computer system. In the mainframe arena, the processor, the computer system, the operating system, the virtual machine manager and to a great extent the main applications were all developed by a single vendor (Bugnion et al., 2012). On the other hand the x86 industry had been totally fragmented into multiple vendors implementing various components mostly with vendor specific designs with least uniformity.

SERVER VIRTUALIZATION TECHNIQUES

Researchers have proposed many virtualization technologies that can be used for hosting multiple systems on a single physical infrastructure. These technologies can be divided into the following groups; they are namely full virtualization, para-

virtualization, hardware-assisted virtualization, operating system virtualization (Zhang, et al., 2010; Bazargan, Yeun, & Zemerly, 2012). All these types of virtualization present different independent virtual machines to the users. In addition to these virtualization techniques, there are other virtualization techniques called storage virtualization, memory virtualization, network virtualization and application virtualization (Gao, Zhang, & Zhou, 2012; Kumar, Reddy, & Rupa, 2012; Costa, Migliavacca, Pietzuch, & Wolf, 2012; Khanna, Beaty, Kar, & Kochut, 2006).

Full Virtualization

Full virtualization creates a complete emulation of the underlying hardware in multiple instances that are presented to the users (Marinescu & Kroger, 2007). Since the full virtualization creates an exact copy of the underlying hardware as virtual machine instances, it is commonly known as the native virtualization. One of the important features of the native virtualization is the complete reflection of the every aspect of the underlying hardware in the virtual machines. every virtual machine instance created by full virtualization will include the complete instruction set, registers, input/output operations, interrupts, memory access etc., of the hardware on which they are hosted. Hence the environment that has been emulated though the full virtualization is an exact copy of the hardware enabling the users to take full advantage of the hardware without requiring any additional knowledge of tweaking. Thus any operating system and application that are supported by the raw hardware can be installed and executed on the virtual machines.

Implementing full virtualization is not a straight forward task as many challenges including security and isolation of virtual machines need to be handled properly. One such challenge that requires the special attention is the execution of privileged instructions evoked by the virtual machines. Privileged operations such as input/output when requested by a virtual machine must

Figure 2. The layered architecture of a fully virtualized system

be intercepted and emulated carefully by the virtual machine manager. The operations invoked by a single virtual machine must be confined to that virtual machine without affecting the status of other virtual machines or the general status of the overall physical system. Only the hardware operations that keep their effects entirely within the virtual machine elements managed by the control programs such as memory locations or arithmetic registers must be allowed to be executed directly on the hardware. All the other operations must be captured and emulated. Figure 2 shows the typical layered architecture of a system installed with full virtualization. From this figure, it can be seen that many different types of operating systems can be installed and executed concurrently on a single hardware system without affecting any one of them. The virtual machine management software executed along with the virtual machine manager would manage the necessary allocation of resources and handle the security between different virtual machines.

Full virtualization has been commonly used for:

- Hosting multiple users on a single computer system;
- Isolating and protecting users from interference;
- Emulating hardware for improved reliability, security and productivity.

Paravirtualization

Paravirtualization is the presentation of a software interface for virtual machines that is slightly different from the underlying hardware (Marinescu & Kroger, 2007). Paravirtualization is also known as the operating system-assisted virtualization as it requires the modification of the guest operating system in order to achieve the successful execution of privileged operations (Ameen & Hamo, 2013). Paravirtualization has been achieved through replacing the non-virtualizable instructions with an alternative set of equivalents that can be easily virtualized. The modification has been intended to speed up the operations that are more difficult to execute in virtualized environments than in real environments. Paravirtualization creates special hooks that are specially defined to allow the guests and host to invoke and recognize those tasks that must be executed in a host domain rather than in the virtual domain. A successful paravirtualized platform makes the design and operation of the virtual machine manager simpler and improves the overall performance of the guest operating system.

The guest operating system to be installed on top of paravirtualized system must be specifically ported for the paraAPI. A conventional OS that has not been designed with special components necessary for running on paraAPI will not run on a paravirtualization VMM. Under para-virtualization, split drivers are used for handling I/O

Figure 3. Paravirtualization

requests. The physical devices are accessed by another set of drivers known as back-end drivers that are part of a privileged virtual machine installed directly on the hardware (Barham et al., 2003). The front-end device driver within the guest operating system would pass the I/O requests from the operating system to the back-end driver in the privileged operating system. The back-end driver will then interpret the request and carry out the task on the hardware directly. Figure 3 shows a system that has been installed with the para-virtualization software. From Figure 3, it can be seen that paravirtualization is similar to full virtualization except for the modification of guest OSs that are running on top of virtual machines.

Hardware-Assisted Virtualization

Hardware-assisted virtualization does not use binary translation as in full virtualization nor hypercalls as in paravirtualization (Shen, Hamayun & Petrot, 2012). Hardware-assisted virtualization is been called by multiple names such as native virtualization, accelerated virtualization or hardware virtual machine. Hardware-assisted virtualization enables full virtualization with maximum efficiency with the aid of the hardware capabilities, especially the processors. Hardware-assisted virtualization provides for a higher level CPU instruction set communication as the hypervisor runs in a new advanced mode known as the root

Figure 4. Hardware-assisted virtualization

mode below the operating system kernel mode. In this virtualization form the critical and privileged instructions are enabled to automatically seize the hypervisor directly. Figure 4 illustrates the hardware-assisted virtualization architecture.

Hardware-assisted virtualization is commonly found in the server market due to its improved performance and security due to high virtual machine isolation. The VMM running on hardware controls and synchronizes the access of the guest operating systems to the hardware resources directly. The advantages of hardware-assisted virtualization include, reduction of maintenance overhead of para-virtualization as no changes to the guest operating system is needed and better performance compared to all other virtualization techniques. The downside of the hardware-assisted virtualization is the requirement of the explicit host CPU support that may not be available in all processors. Also a pure hardware-assisted virtualization approach suffers from high CPU overheads that limit the scalability and the efficiency of server consolidation due to many virtual machine traps involved.

Operating System Level Virtualization

Operating system level virtualization also called the Single Kernel Image (SKI) runs multiple

instances of the same host operating systems in parallel (Bazargan et al., 2012). Thus, it can be concluded that it is not the hardware that has been virtualized but the host OS is. All virtual machines running on the same hardware must execute the same virtualized operating system image. Figure 5 shows the architecture of the OS level virtualization. The virtualized operating system image is known as the virtualization layer.

The OS level virtualization reduces the administration effort needed for managing the system by allocating the resources both at creation of a virtual machine as well as at runtime. The OS layer virtualization is more efficient than other hardware level virtualizations but suffers from the shortcomings of reduced isolation between different virtual instances and lack of freedom for installing different OSs other than the host OS.

Storage Virtualization

Under storage virtualization, multiple disk drives are combined into a single logical drive and presented to the hosting system as such (Gao et al., 2012). Storage virtualization can be divided into two primary types. They are namely, file virtualization and block virtualization. Block virtualization separates logical storage from the physical storage that helps flexible access to the

Figure 5. Operating system-level virtualization

storage system without worrying about the details of the physical arrangement of the disks (Wooley, 2011). File virtualization operates at file level rather than block level or disk levels (Joukov et al., 2007). File virtualization makes the data accessed at file level independent from the physical location of the files. This helps the optimization of storage use through server consolidation and the migration of files from one system to another with minimum disruptions.

Storage virtualization may be carried out within a single computer, within a local area network or across multiple local area networks (Peng, Zhu & Luo, 2012). The storage that is directly attached to a server is known as Direct Attached Storage (DAS) (Yuan, 2011). In DAS the storage device is directly attached to the host computer by a cable. The internal disk drive of a computer or a directly attached tape drive is the simplest form of DAS. The access to the storage device is carried out through I/O requests that access devices directly. When a storage device along with a special integrated processor for handling data access requests is connected to the network directly, it is called Network Attached Storage (NAS) (Peng et al., 2012). The data access through a NAS device is carried out with the aid of specialized protocols. The NAS processor attached with the storage device translates will the file requests received from clients to device I/O requests. When the storage devices are housed in a special network and access to them is provided through a gateway, it is called a Storage Area Network (SAN) (Chishima, Yamaguchi & Oguchi, 2007). Similar to DAS, in SAN also data access is carried out through direct I/O requests.

Memory Virtualization

Similar to physical computers, even virtual machines require memory dedicated for them to keep the active programmes including the operating system, applications and other processes (Ali & Meghanathan, 2011). The total size of memory required is equal to its configured size and the

overhead required for virtualization. The configured memory is the amount of RAM including both physical and virtual memories made available to the guest operating system for hosting the applications and other processes (Kumar et al., 2012). For creating memory virtualization the VMM running host computer partitions the physical and virtual memory space of the host system. These portions of memory are isolated from each other in order to provide the required security for protecting them from interfering with each other.

For the virtual machines to work smoothly the virtual memory addresses used by the virtual machines must be translated to physical memory addresses. Address translation in virtual machines are carried out using several mapping techniques such as Extended Page Table (EPT), Shadow Tables (ST), Nested Page Table (NPT) etc., (Wang, Zang, Wang, Luo & Li, 2011). The conventional method of address translation is using shadow page tables. The VMM maintains a shadow page table for every virtual machine where the mapping of every virtual address to physical address is maintained. In addition to the shadow page table maintained by the VMM, every guest also maintains its own virtual to physical mapping table. The shadow mechanism carried out through shadow pages table suffers from the shortcoming of VM exits at times of page faults that require synchronization between two page tables. In order to avoid the VM exits, vendors like Intel and AMD have developed other techniques such as hardware assisted EPT and NPT for facilitating address translation. In hardware assisted techniques, the Memory Management Unit (MMU) manages a guest page table that maps the virtual addresses to physical addresses of the guests. In the hardware assisted techniques, a guest page fault is managed by the guest itself protecting the system from VM exits.

Network Virtualization

Network virtualization refers to the combination of network hardware and software into a single

virtual network (Bazargan, et al., 2012). When network virtualization has been implemented, it hides the details of the network implementation and provides a unified view that can be customized through a software interface to suit the user requirements.

Application Virtualization

Application level virtualization presents the user with a copy of components that are not shared with other processes. The components commonly protected this way include registry files, global objects, local variables and personalized environmental settings. The virtual environment prevents conflicts with other instances of the same application running in parallel on the same system. Java Virtual Machine (JVM) is an example of application level virtualization. The following sections briefly describe the different virtualization technologies.

QUALITY OF SERVICE ISSUES IN VIRTUALIZATION

Since virtualization is the underpinning technology that powers the revolutionary cloud computing paradigm, the quality of service of virtualization will decide the quality of cloud computing as well. It is a fact that a virtualized system cannot offer performances equal to that of a system running with native resources (Rao & Rao, 2015). Hence it is vital to ensure the quality of service in virtualization, if it is to provide a guaranteed service to customers while maintaining maximum efficiency and utilization of the resources (Calheiros, Ranjany & Buyya, 2011). Calheiros et al., (2011) further state that the achieving the required QoS targets agreed upon in the SLAs signed between the customers and service providers is often complicated due to many issues including the uncertain behavior of virtualized IT resources

and network elements. The leading hypervisors in the market such as Xen employ fair schedulers that manage the job allocation based on pointers or weights assigned by the administrators (Rao & Rao, 2015). The performance of the jobs thus scheduled is very sensitive to these scheduling parameters. The main downside of this scheme is the static nature of these pointers that cannot take the dynamic nature of the application requirements. It must be noted that the exact relationship between the domain parameters and performance measures such as response time or throughput are neither obvious nor static. Also, the resource provisioning by servers may encounter many unpredictable situations that obstruct the smooth delivery of application services at run times. The problem is further compounded in large public data centers by the dynamic and unpredictable workload behavior with spikes depending on the time of day, application popularity, customer characteristics and expectations etc. Hence, if the cloud systems need to meet the demands of the customers, the underlying technology that enables the cloud operations possible must be designed in such a manner that it can respond to the variations positively and promptly.

VIRTUALIZATION SECURITY

Despite the advantages the virtualization technologies provide the users, they have certain drawbacks too, if not handled properly. Security is one of the main issues that must be given special attention when setting up a virtualized system. Some of the most common security issues identified with virtualization include virtual machine escape, virtual machine hopping, malicious code injection, hyperjacking, virtual machine sprawl, side channel attacks, virtual machine poaching and unsecured virtual machine migration (Kedia, Nagpal & Singh, 2013; Kapadia & Gulati, 2014).

FUTURE RESEARCH DIRECTIONS

Virtualization area provides the researchers ample opportunity for further research into the foreseeable future. The following are some of the directions, which the future research can be directed to:

- **Virtualization Security:** Many guest systems are loaded on top of a single hardware platform sharing the resources. So, the security of the loaded systems and applications may be compromised through leaks and attacks. Hence further research into the system isolation and security is needed for achieving complete isolation between hosted systems while efficiently sharing the common resources.
- **Energy Optimization:** Datacenters have been identified as the entities to have large energy footprints. Largest amount of energy is consumed during the switching on and off phase of virtual machines. Hence the energy efficient virtual machine allocation provides an opportune area for future researchers.
- **Efficient Virtual Machine Allocation:** Cloud computing obtains its advantages through efficient management of hardware resources. Hence efficient allocation and reallocation of virtual machines on the fly is a must. Thus, this area too provides opportunities for the development of new and improved virtual machine allocation strategies, mechanisms and schemes.
- **Elastic Resource Management:** Effective elastic resource management requires the consideration of many areas including resource allocation, resource provisioning, resource mapping and resource adaptation. Hence extensive future research is needed in these areas to come up with effective and efficient elastic resource management schemes.
- **QoS in Virtualized Systems:** Real-time business applications generally have very

stringent QoS requirements. Implementing QoS in virtualized environments would determine the success of the entire cloud computing landscape. Hence, there are many avenues for future research in the area of virtualization service quality.

CONCLUSION

This chapter took an in depth look at virtualization from the points of their advantages, disadvantages, different types and implementation schemes. The chapter also looked at the history of virtualization in order to present a complete picture of this ground breaking technology starting from the IBM's mainframe based virtual machines to today's virtualized systems implemented on various hardware platforms and resources. This chapter also briefly highlights the quality of service and security issues that might affect the performance of virtualized systems.

KEY WORDS AND DEFINITIONS

Attack: It is an attempt to gain unauthorized access to, steal, expose, alter, disable or destroy computing resources by unauthorized personnel or through unauthorized means.

Cloud Computing: It is the newest paradigm in computing that delivers the resources including hardware, platform and application as services.

Elasticity: It is the capability of a computer system to adjust its capacity dynamically to cater to the demands of users.

Infrastructure as a Service: It is a service provided through cloud computing technology where users can access virtualized hardware and pay on a utility basis.

Multiple Tenancy: Refers to accommodating multiple users on a single hardware system and enabling them to access the underlying resources as if they are the sole users.

Quality of Service: Refers to the capability of a system to provide services to customers within the expected limits of user preference.

Security: Denotes the protective mechanisms including policies, guidelines and algorithms applied to computers, computer networks, users and data stored and transmitted over them.

Virtualization: It is the process of creating multiple logical hardware replicas based on an underlying infrastructure and assigning them to different users.

Communications Theory

Communication, Information, and Pragmatics

Adriana Braga

Pontifical Catholic University of Rio de Janeiro, Brazil

Robert K. Logan

University of Toronto, Canada

INTRODUCTION

The intention of this article is to clarify the relationship between communication and information by considering pragmatics. Although these terms are closely related, they are not the same. In order for communication to occur the information that is transmitted must be processed within the social context of the sender and the receiver or in other words through the use of pragmatics. That is, there is no communication between the sender and the receiver if the receiver does not understand the information sent by the sender. Information before it is interpreted is therefore nothing more than the signal. It only becomes communication, if it is properly interpreted by the receiver of the information. And it is only through the context or the pragmatics that the receiver can understand the intended meaning of the sender and therefore as a result communication can take place. Misinterpretation leads to miscommunication. As no interpretation is perfect as pragmatics between the sender and the receiver is never perfect the content of the communication depends on the user and the user's interpretation, which McLuhan formulated with his iconic one-liner *the user is the content*. In actuality the sender, the receiver and their understanding of each other are all part of the content.

BACKGROUND

The context in which the information is interpreted is the only way that the meaning that was intended by the sender can be understood by the receiver, but the meaning that the receiver attaches to the information sent by the sender will always vary to some degree (Chan, Walker & Gleaves, 2015; Gibbs et al, 2015; Gui & Argentin, 2011; Introna & Nissenbaum, 2000). Because the 'user is the content' all communication is miscommunication to a certain degree. Perfect communication is an ideal that all communicators strive to achieve through the art of rhetoric. To sum up what we have just posited: information is required for communication but does not necessarily result in communication and never results in perfect communication. The extra ingredient that is required to transform information into communication is context or pragmatics, which is never perfect. Recent methodological innovations try to account for the pragmatics on digital environments (Boyd and Crawford, 2012; Hine, 2005; Lee and Chen, 2015).

In this article we will first examine the meaning and significance of information, which will entail a critique of Shannon Information Theory. We will show it is really a theory of the transmission of signals. We describe how MacKay and Bateson with their respective formulations of "information

is the distinction that makes a difference (MacKay, 1969)” and “information is the difference that makes a difference (Bateson, 1973)” adds the element of meaning to the definition of information. We then examine the proposition of Kauffman, Logan et al. (2007) that organization is a form of information and that life entails the propagation of organization.

Assuming that it is not possible not to communicate, we emphasize the pragmatic dimension of communication. We argue that ‘information,’ ‘communication’ and ‘social interaction’ are inseparable elements of production of meaning, even if analytically they can be conceived as independent concepts. Thus, as in any communication there are three simultaneous dimensions operating as a system – syntactic, semantics and pragmatics, and it is also the case that ‘information,’ ‘communication’ and ‘social interaction’ are operating as a system. In this sense, speech acts owe their meaning to performances in the context of what information the sender sends, the interpretation of the receiver and the social context that exists between the sender and the receiver. We argue that, from the differential emphasis on the syntactic, semantic or pragmatic dimensions of communication, lies a major difference between models for the theory of communication: communication as transmission of information or communication as a relational activity.

Information: From Origins to Shannon’s Information Theory

The English word information according to the Oxford English Dictionary (OED) first appears in the written record in 1386 by Chaucer. It is derived from Latin through French by combining the word “inform” meaning “giving a form to the mind” with the ending “ation” denoting a noun of action. This earliest definition refers to information as an item of training or molding of the mind. Information is not an object but a process of forming or informing the mind.

The notion of information as something capable of storage in or the transfer to something inanimate and the notion of information as a mathematically defined quantity does not arise until the 20th century. The beginning of the modern theoretical study of information is attributed to Claude Shannon (1948), who is recognized as the father of information theory. He defined information as a message sent by a sender to a receiver. Shannon wanted to solve the problem of how to best encode information that a sender wished to transmit to a receiver. Shannon gave information a numerical or mathematical value based on probability defined in terms of the concept of information entropy more commonly known as Shannon entropy. Information is defined as the measure of the decrease of uncertainty for a receiver. The amount of Shannon information is inversely proportional to the probability of the occurrence of that information, where the information is coded in some symbolic form as a string of 0s and 1s or in terms of some alpha-numeric code.

MacKay’s Counter Revolution: Where Is the Meaning in Shannon Information?

According to Claude Shannon (1948) his definition of information is not connected to its meaning. However, as Shannon suggested, information in the form of a message often contains meaning but that meaning is not a necessary condition for defining information. So it is possible to have information without meaning, whatever that means.

Not all of the members of the information science community were happy with Shannon’s definition of information. Three years after Shannon proposed his definition of information Donald Mackay (1969) suggested that information should be defined as “the change in a receiver’s mind-set,” and thus with meaning. He defined information as “a distinction that makes a difference.” and not just the sender’s signal (Hayles, 1999). The notion of information independent of its meaning or context is like looking at a figure isolated from its ground.

As the ground changes so too does the meaning of the figure. This is a central idea of Marshall McLuhan's (1964) approach to communications known as media ecology.

[McLuhan] believed that to understand the meaning of a figure one must take into account the ground in which it operates and in which it is situated. The true meaning of any "figure," whether it is a person, a social movement, a technology, an institution, a communication event, a text, or a body of ideas, cannot be determined if one does not take into account the ground or environment in which that figure operates. The ground provides the context from which the full meaning or significance of a figure emerges. The concern with the figure/ground relationship is consistent with McLuhan's emphasis on interface and pattern rather than on a fixed point of view (Logan 2011, p.2).

The problem with MacKay's definition was that meaning could not be measured or quantified and as a result the Shannon definition won out and changed the development of information science. The theorizing that Shannon conducted through his combination of electrical engineering and mathematics came to be known as information theory. It is ironic that the OED cites the first use of the term "information theory" as that of MacKay's who used the term in a heading in an article he published in the March 1950 issue of the Philosophical Magazine. Gregory Bateson (1973) defined information as "the difference that makes a difference," which is now more often quoted than MacKay's formulation. Both MacKay's and Bateson's formulation contain the notion that it is the meaning of the information that makes the difference. Another one-line definition of information that incorporates the notion of its meaning is Fredkin's "The meaning of information is given by the processes that interpret it." This is a very insightful definition because it explicitly incorporates the notion that information depends on context.

If information is the distinction (MacKay) or the difference (Bateson) that makes a difference then if there is no distinction or no difference then there can be no information. This would mean chaos or random numbers contain no information because there is no difference or distinction in one part of the stream of numbers as opposed to another part of the stream because of a lack of organization. This is opposite to the conclusion of Shannon who claims that a stream of random numbers contains the maximum information. While it is true each element is different from the next and is a complete surprise it is also true that the overall pattern of chaos and randomness is the same and hence there is no distinction nor is there any difference in the stream of random numbers.

Feedforward and Cybernetics

I. A. Richards' area of research was rhetoric, which he considered to be more than just the art of persuasion. Richards was concerned with the accuracy of human communication. He considered the field of rhetoric to be about finding remedies for avoiding misunderstandings and hence improving communication as well as understanding how words work. He believed the notion of feedforward was an important tool for achieving these ends. Feedforward is basically a form of pragmatics where pragmatics is the use of context to assist meaning.

Richards first introduced the term feedforward in his address to the Macy conferees in 1951:

Perhaps this thing on which I want to put the spotlight will be considered to be included in some ingenious way under the word "feedback." But what I am going to stress stands in an obvious and superficial opposition to "feedback," and it will, in certain frames of thought, be given nearly, if not quite so much, importance, and sometimes more importance than feedback itself in certain connections. It is certainly as circular. You have no doubt fed forward enough to see that what I am going to talk about from now on is feedforward.

I am going to try to suggest its importance in describing how language works and, above all, in determining how languages may best be learned (Richards, 1952, p. 54).

The coining of the term by Richards was no doubt influenced by the term feedback used by cyberneticians and according to the OED first introduced into the English language in 1920. But as Richards pointed out feedforward stands in superficial opposition to feedback. Feedback is basically reactive whereas feedforward is proactive. Feedforward anticipates where one is headed and sets one's goals. Feedback allows one to see how close one gets to their goals. Richards who stressed the importance of providing the context of what one wanted to communicate might have coined the term feedforward to complement the term feedback used by cyberneticians precisely because the audience that he was addressing at the Macy Conference included the man who coined the term cybernetics, namely Norbert Wiener. The term feedforward as used by Richards suggested that in order to have one's communication understood it was necessary to literally feedforward the context of what one was planning to talk about.

Organization as Information

In an article entitled Propagating Organization: An Enquiry (POE) Kauffman, Logan, Este, Goebel, Hobill and Shmulevich (2007) argued that Shannon's (1948) classical definition of information as the measure of the decrease of uncertainty was not valid for a biotic system that propagates its organization. The core argument of POE was that Shannon information "does not apply to the evolution of the biosphere" because Darwinian preadaptations cannot be predicted and as a consequence "the ensemble of possibilities and their entropy cannot be calculated." Therefore a definition of information as reducing uncertainty does not make sense since no matter how much one learns from the information in a biotic system the uncertainty remains infinite because the number

of possibilities of what can evolve is infinitely non-denumerable. This contradicts Shannon who specified that the number of possible messages was finite.

Instead of Shannon information we defined a new form of information, which we called instructional or biotic information, not with Shannon, but with constraints or boundary conditions. The amount of information will be related to the diversity of constraints and the diversity of processes that they can partially cause to occur. By taking this step, we embed the concept of information in the ongoing processes of the biosphere, for they are causally relevant to that which happens in the unfolding of the biosphere.

We therefore conclude that constraints are information and... information is constraints... We use the term 'instructional information' because of the instructional function this information performs and we sometimes call it 'biotic information' because this is the domain it acts in, as opposed to human telecommunication or computer information systems where Shannon information operates (Kauffman, Logan, et. al., 2007).

A living organism is an open system, which von Bertalanffy (1968) "defined as a system in exchange of matter with its environment, presenting import and export, building-up and breaking-down of its material components." Instructional or biotic information may therefore be defined as *the organization of that exchange of energy and matter*. The fact that a biotic system is an open system can be used to argue against the association of instructional or biotic information with cybernetics because cybernetics focuses strictly on the flow of information and does not deal with the flow of energy and matter.

In POE it has been the associated biotic or instructional information with the organization that a biotic agent is able to propagate. This contradicts Shannon's definition of information and the notion that a random set or soup of organic chemicals has more Shannon information than a

structured and organized set of organic chemicals found in a living organism.

The biotic agent has more meaning than the soup, however. The living organism with more structure and more organization has less Shannon information. This is counterintuitive to a biologist's understanding of a living organism. We therefore conclude that the use of Shannon information to describe a biotic system would not be valid. Shannon information for a biotic system is simply a category error. A living organism has meaning because it is an autonomous agent acting on its own behalf. A random soup of organic chemicals has no meaning and no organization (Kauffman, Logan, et. al., 2007).

According to Shannon's definition of information a set of random numbers transmitted over a telephone line would have more information than the set of even numbers transmitted over the same line. Once 2, 4, 6, 8, 10, 12 was received the receiver would be able to correctly guess that the rest of the numbers to follow the sequence would be the set of even numbers. The random numbers have no organization but the even numbers are organized so the mystery of the relevance of Shannon information deepens, as one must counter-intuitively conclude that information and organization can be at cross-purposes in Shannon's scheme of things.

This argument completely contradicts the notion of information of a system biologist who would argue that a biological organism contains information. It is by virtue of this propagating organization that an organism is able to grow and replicate, as pointed out by Kauffman (2000) in *Investigations*. From the contradiction between Shannon and biotic information we already have a hint that there is possibly more than one type of information and that information is not an invariant like the speed of light in relativity theory, which is independent of its frame of reference. We also see that perhaps Shannon's definition of information might have limitations and might not represent a universal notion of information. After all Shannon formulated his concept of information as information entropy to solve a specific

problem namely increasing the efficiency or the signal to noise ratio in the transmission of signals over telecommunication lines.

The term information is generally regarded as some uniform quantity or quality, which is the same for all the domains and phenomena it describes. In other words, information is an invariant like the speed of light, the same in all frames of reference. But as Kauffman, Logan et al. (2007) have argued the notion of Shannon information and biotic information are quite different.

Is It Possible Not to Communicate?

Living beings (be they bacteria, plants, fish or humans) interact with their environments by reacting to stimuli, that is, by defining their immediate surroundings and adapting their conduct to them. That means interpretation of signs, processing of information and choosing a definite line of conduct. That is, *communicating* with their environment. In the same way that syntax, semantics and pragmatics are inseparable in communication phenomena, information, communication and interaction are inseparable in biotic systems, human culture included.

Action is innate in humans, and is not just a reaction. Meaning is foundational for the direct feeling and perception of "reality". Meaning is not inherent in the objects, but the ownership of the propositions, statements, and beliefs belongs to the receiver through their interpretations of the originating signals of the sender. The sense of presence in the world presupposes a real world through experience.

Meaning is not inherent to objects, but attributed by people in particular social situations. Additionally, the attribution of meaning to things never ceases. In the presence of another person, an object, a message or a social situation, an individual immediately tries to define the situation and attribute to it a meaning in the context of the immediate situation.

Assuming that it is not possible not to communicate, we emphasize the pragmatic dimension

of communication. We argue that ‘information,’ ‘communication’ and ‘social interaction’ are inseparable elements of production of meaning, even if analytically they can be conceived as independent concepts. Thus, as in any communicational process there are three simultaneous dimensions operating as a system – syntactic, semantics and pragmatics, and it is also the case that ‘information,’ ‘communication’ and ‘social interaction’ are operating as a system. In this sense, speech acts owe their meaning to performances in the context of what information the sender sends, the interpretation of the receiver and the social interaction that exists between the sender and the receiver.

The pragmatist motto of Peirce states that the production of meaning is oriented to action, and that the idea of what a thing ‘is’ lies on the somatry of the effects that can be conceived as possible from it.

Beside this two main branches of pragmatist philosophy, there is also the approach of Ludwig Wittgenstein (mainly in his *Philosophical Investigations*, 1953), in which the meaning of an expression lies on its practical uses; that of John Austin (1962) and John Searle (1965), in which ordinary language is seen as a resource for philosophical analysis, as well as those who see in pragmatism an adequate technical resource for the renewal of a transcendent philosophy of communication, such as Jurgen Habermas (1984) and Karl-Otto Apel.

According to Charles W. Morris, a semiotician and disciple of George Herbert Mead, the study of language has been traditionally divided between: a) a semantic approach, dealing with the relation of signs with the things they represent, that is, of signs with their meaning; and b) a syntactic approach, dealing with the relation of signs with other signs, such as the relation between words within a sentence, searching for the rules that ensure its meaning.

To Morris, both approaches do not solve neither the problem of meaning nor the problem of truth. Thus, a third approach – pragmatics – is needed to

deal with the relation of signs with its users, that is, of sentences with the people who speak them.

The main concepts of a pragmatist approach towards language are, thus, missing concepts in semantic and syntactic approaches.

Thus, under a pragmatist perspective, communication is inseparable from the social act in which it is embedded. Communication is the mediation that allows collective social action. G. H. Mead’s masterpiece *Mind, Self and Society* (1934) expresses in its title the central spots from which he understands human activity. ‘Mind,’ ‘Self’ and ‘Society’ are different elements of the same social process, his basic analytical units.

To Mead, the *act* (a complete unit of human conduct) derives from an impulse that produces perception, attribution of meaning, evaluation by participants and a final outcome: a process, which cannot be analyzed from just one of its parts. Mead’s notion of society presupposes conscious individuals, who actively interpret the world in a never-ending relational process.

FUTURE RESEARCH DIRECTIONS

The understanding of information as an inseparable part of the integral process of meaning production converges to some of the most urgent and imperative demands of our era. We live in a society of individuals, of advancing of human and political rights and a fast pace of technological development. The outcomes of the process of cultural integration to the newest technology of communication are yet unconcluded and unknown (Braga & Logan, 2014; Hargittai & Hinnant, 2008; Livingstone, 2004; Park, 2012; Van Deursen & Van Dijk, 2010, 2015; Van Dijk, 2005).

Thus, research on Human-Computer-Interaction (HCI) may have a significant development if it includes into its research agenda the sensibility to social contexts in which its phenomena take place.

Future research directions would include a re-evaluation of the use of Shannon Information

theory in the various disciplines in which it has been implemented to determine in what manner information and signal have been conflated. A signal no matter how accurately it has been transmitted and how accurately its information content has been calculated using Shannon's mathematical formula still has no meaning if the context or the pragmatics has not been also considered.

Another research trend to be explored regards the role of technologies of information and communication in social environments, where those technologies are essential to their organization, strategic development and their outcome.

CONCLUSION

What is communication? There are two alternative communication concepts that have coexisted since the term began to be used in the mid-nineteenth century: "communication as transmission" and "communication as ritual". Trying to answer the difficult question: what is communication?, Carey states that "communication is a symbolic process whereby reality is produced, maintained, repaired and transformed" (1989, p. 23) This definition challenges the notion (of Cartesian origin) that there is a dualism between 'fact' and 'discourse', between 'reality' and 'language.' 'reality' is a symbolic, social product. "The reality is constructed by communication through the use of symbolic forms." (Carey, 1989, p. 25)

All these distinctions, apart from their metaphorical subtleties, point out to the difference between a group of communication theorists who see communication as a matter of *transmission of information* (that is, syntax + semantics), and, on the other side, a group of theorists that regard communication as a matter of *social interaction* (syntax + semantics + pragmatics). In the first group, focusing on 'information', people (the "audience" or the "public") are seen as simple recipients receiving their messages, regardless of what they can actually do or think about it. The

second group of theorists, in order to account for the pragmatics of social situations of 'follow the actors', integrate cultural approaches with communication practices. (Braga, 2008)
